## Information Gaps and Shadow Banking

Kathryn Judge

The healthy functioning of most financial markets depends on the willingness of market participants to acquire financial claims without complete information about the assets underlying those claims. Equity and money markets resolve this challenge in fundamentally different ways. Equity markets, like the New York Stock Exchange, “level up” the informational playing field through publicly observable prices that contain meaningful information about the value of underlying assets. This works because the same processes that reward sophisticated investors for engaging in costly information gathering move prices to more efficient levels. Money markets, by contrast, “level down” the informational playing field through claim structures that make it costly and unrewarding for claimants to acquire superior information about the underlying assets. A person acquiring a money claim, such as a bank deposit or shares in a money market mutual fund, instead relies on a proxy indicating that the claim is exceptionally low risk coupled with a right to exit, quickly and at face value, as a substitute for perfect information. This makes money markets highly liquid most of the time but it also contributes to their inherent instability. In synthesizing insights from financial economists and legal academics and examining the regulatory architecture in light of those understandings, this Article provides the first comprehensive account of the ways that the distinct informational incentives of equity and money claimants can explain much of securities and bank regulation.

This Article uses this foundation to reveal the fundamental mismatch between the existing financial regulatory paradigms and the distinct challenges posed by the large and growing “shadow banking system.” The shadow banking system fulfills many of the economic functions long played by banks but because it operates largely in the capital markets, it is largely governed by the disclosure-oriented rules that arose to govern equity markets. As a result, there are structural reasons to expect shadow banking will lead to large information gaps, that is, pockets of pertinent and theoretically knowable information that is not actually known by any market participant or regulator. The Article further shows how information gaps can render a system more vulnerable to a panic and impede the market-based and regulatory processes that can help restore stability once a panic takes hold. By demonstrating how shadow banking leads to information gaps and the ways those gaps contribute to fragility, this Article sheds new light on the regulatory challenges posed by shadow banking.

### Introduction

Traditionally, the United States has had two parallel regimes for moving capital from persons who have it to persons who need it—the capital markets and the banking system. Both regimes served the socially useful function of providing financing for productive undertakings, but each raised capital through the issuance of different types of financial claims. The paradigmatic claim issued in the capital markets is an equity claim, while most of the capital in the banking system came from the issuance of

money claims.<sup>1</sup> Equity claims, such as common stock issued by a public corporation, are perpetual claims, the value of which can fluctuate significantly and is realized only through trading in a secondary market. In contrast, money claims, which include familiar instruments like the demand deposits issued by banks and more innovative instruments like commercial paper backed by highly rated collateral, are very short-term instruments with values that do not meaningfully fluctuate and which allow the holder to walk away at anytime. The different types of financial claims used to raise capital in each domain also helped enable each to play distinct additional roles: The capital markets produced information and facilitated corporate governance while banks served as the backbone of the payment system and facilitated liquidity and maturity transformation.<sup>2</sup> This difference also contributed to the evolution of two very different regulatory regimes.<sup>3</sup> As reflected in the stability of the financial system between the Great Depression and the 2007–2009 financial crisis (the Crisis), this overall scheme worked exceptionally well for a long period of time.

The Crisis wreaked havoc on the financial system and revealed a third systemically important regime—the shadow banking system. The shadow banking system is an intermediation regime that resides in the capital markets while serving many of the economic functions traditionally fulfilled by banks.<sup>4</sup> With the benefit of hindsight, it is evident that this system had been growing for decades prior to the Crisis.<sup>5</sup> Nonetheless, it was only during the Crisis, which revealed this regime to be inherently fragile and capable of bringing down the rest of the financial system, that experts started to appreciate its distinctiveness and importance.<sup>6</sup> Recent estimates suggest that the shadow

<sup>4</sup> How best to define the shadow banking system is a matter of ongoing debate. This Article makes no effort to resolve this issue, as the dynamics here at issue are widely recognized as core to shadow banking however defined. *E.g.*, MORGAN RICKS, *THE MONEY PROBLEM: THE MONETARY ORIGINS OF FINANCIAL INSTABILITY* 103-45 (forthcoming 2016) (on file with author) [hereinafter RICKS, *THE MONEY PROBLEM*] (explaining that the term “‘shadow banking’ ... has come to mean different things to different people,” but at the Treasury Department during the Crisis, “the term meant ... the financial sector’s use of vast amounts of short-term debt [i.e., money claims] to fund portfolios of financial assets”); ZOLTAN POZSAR ET AL., FED. RESERVE BANK OF N.Y., STAFF REP. NO. 458, *SHADOW BANKING*, at 1 (2010), available at <http://ssrn.com/abstract=1645337> (explaining how “the shadow banking system provide[s] sources of funding for credit by converting opaque, risky, long-term assets into money-like, short-term liabilities”); Steven L. Schwarcz, *Regulating Shadow Banking: Inaugural Address for the Inaugural Symposium of the Review of Banking & Financial Law*, 31 REV. BANKING & FIN. L. 619, 623, 626 (noting that “we lack a concrete definition of shadow banking” while also emphasizing that “a high level of institutional demand for (especially) short-term debt instruments” was a critical factor in the growth of what is now “known as the ‘shadow banking system’”).

banking system in the United States is larger than the banking system and poised for further growth.<sup>7</sup> One reason for this growth is that companies and institutional investors today hold more cash than they ever have historically and they want to place much of this cash into money claims,<sup>8</sup> but banks are not suited to accept deposits in such large amounts.<sup>9</sup> How best to regulate this system is one of the most pressing issues in financial regulation today.<sup>10</sup>

This Article contributes to that project in two ways. First, it demonstrates why neither of the existing paradigms for financial regulation can address the distinct challenges posed by shadow banking. Second, it shows how the information gaps that this Article identifies as endemic to shadow banking system contribute to its fragility. In the process of exploring these issues, the Article also reveals and addresses an important shortcoming in current theoretical understandings of how the distribution of information affects market functioning.

The Article begins by providing the first comprehensive account of how securities and bank regulation have evolved to address the informational needs of the equity and money claimants, respectively. Equity claimants are strongly incentivized to gather and analyze information.<sup>11</sup> Securities regulation harnesses and facilitates these inclinations through a regime that relies on market participants to assess the value of assets underlying equity claims. The primary role of regulation is to facilitate these market-based processes.<sup>12</sup> Money claimants, by contrast, tend to be skittish and minimally informed.<sup>13</sup> The banking system addresses these dynamics through the creation of a powerful body of regulators authorized to limit bank activities, supervise bank operations, provide liquidity

to a healthy bank facing excessive withdrawals, and close a bank down if its financial health becomes too precarious.<sup>14</sup> In each case, someone has high-quality information about the undertakings being funded by the capital coming into the system, the nature of the associated risks, and the ability to take actions responsive to those risks.

The same is not true with respect to shadow banking. The shadow banking system is an interconnected web of institutions that operates largely in the capital markets. This means that the default regulatory regime governing the shadow banking system is the disclosure-oriented regime designed to govern equity claims and other investments.<sup>15</sup> But money claimants do not have the same incentives as equity investors—they will walk away before engaging in meaningful information collection and analysis.<sup>16</sup> This has little to do with the claimants, who are often the same sophisticated parties that undertake the information-generating activities that promote efficiency in the equity markets. Rather, it is inherent in the nature of money. A financial claim ceases to function as money if the holder perceives there to be any meaningful credit risk, or even if the holder is uncertain about the amount of credit risk a claim poses.<sup>17</sup> In contrast to the banking system, however, there is no body of informed and powerful regulators who can step in to assure money claimants or minimize the effects of their departure because there is no comparably robust oversight regime. As a result, it will often be the case that *no one* has high-quality information about the assets underlying the shadow banking system, how risks are allocated across that system, and other pertinent information.

In undertaking this structural analysis, this Article reveals a shortcoming in the conceptual toolkit used to analyze how information and ignorance affect market functioning. One of the frames most commonly used to examine these dynamics focuses on how information is distributed among parties. When one person has information, a second lacks it, and costs or other frictions limit the first person's ability to credibly convey that information to the second the result is an "information asymmetry." As George Akerlof famously demonstrated using the used car market, in a world where some assets are lemons, others are cherries, and a seller knows more than would-be buyers about which type of asset she is selling, information asymmetries can prevent otherwise efficient transfers.<sup>18</sup> A second common paradigm builds on a dichotomy proposed by Frank Knight for categorizing information that is pertinent but lacking. In Knight's analysis, when the "the distribution of the outcome in a group of instances" is known, it is a risk; uncertainty, by contrast, is "not susceptible to measurement."<sup>19</sup> The risk-

<sup>18</sup> George Akerlof, *The Market for Lemons: Quality Uncertainty and the Market Mechanism*, 84 Q.J. ECON. 488, 495–96 (1970). Others have shown that modest information asymmetries can actually facilitate market functioning, as the ability to capitalize on informational advantages can play a critical role incentivizing market participants to engage in costly information collection and analysis. See *infra* Part III.B.

<sup>19</sup> FRANK H. KNIGHT, RISK, UNCERTAINTY AND PROFIT 232 (2006 republication of 1957 ed.). True Knightian uncertainty is usually presumed to be unknowable. *E.g.*, Eric L. Talley, *On Uncertainty, Ambiguity and Contractual Conditions*, 34 DEL. J. CORP. L. 755, 759 (2009) (explaining that "[r]isk' refers to randomness whose probabilistic nature is extremely familiar and can be characterized with objective probabilities" whereas uncertainty "refers to randomness whose probabilistic behavior is extremely unfamiliar, unknown, or even unknowable"); Daniel A. Farber, *Uncertainty*, 99 GEO. L.J. 901, 901 (2011) ("Economists distinguish

uncertainty dichotomy is useful because there are tools that can be used to manage risks that are not available when one is instead confronting an “unknown unknown.”

The shadow banking system creates an informational challenge not captured in either of these frames or the more extensive literature on information and market functioning. Because much of the capital flowing into the system comes from minimally informed money claimants but there is no robust oversight regime, shadow banking results in large pockets of pertinent and theoretically knowable information not actually known by any market participant or regulator. This Article identifies such “information gaps” as a distinct and important type of information dynamic. The analysis provides further evidence of the need to delineate this dynamic more precisely by showing that during the Crisis, policymakers often used the terms information asymmetry and uncertainty to describe dynamics that are more accurately characterized as information gaps.<sup>20</sup> The distinction is critical, as the types of market forces that will be operational and the policy levers available to regulators are different when the challenge is one of knowable but unknown information.<sup>21</sup>

A primary reason that information gaps can grow so large in the shadow banking system is that the effects of information gaps on market functioning are state contingent.<sup>22</sup> Because the shadow banking system is built on money claims, a high degree of ignorance among persons holding money claims is the norm. Information gaps thus do little to detract from market functioning so long as confidence reigns and may even facilitate it.<sup>23</sup> In the face of a signal that raises doubt about whether money claims are backed by sufficient collateral, however, the situation changes dramatically. Information gaps increase the probability of widespread panic. This fragility arises because money claimants will run not only when the increased credit risk so justifies, but also when information gaps prevent money claimants from being able to assess, with the minimal effort they can rationally invest, whether the claims they hold are among those exposed to the newly revealed risk.<sup>24</sup> Runs on shadow banks may look different than the long lines of anxious depositors of depicted in *It's a Wonderful Life*, but the underlying economics are quite similar, as are the devastation such runs can wreak on the broader financial system.<sup>25</sup>

Accentuating the systemic risk emanating from information gaps is the way those gaps impede the market and regulatory processes that can blunt the adverse effects of a

between ‘uncertainty’ (where the likelihood of the peril is nonquantifiable) and ‘risk’ (where the likelihood is quantifiable).”); MILTON FRIEDMAN PRICE THEORY: A PROVISIONAL TEXT 282 (1976 ed.) (“In his seminal work, Frank Knight drew a sharp distinction between risk, as referring to events subject to a known or knowable probability distribution and uncertainty, as referring to events for which it was not possible to specify numerical probabilities.”). This may elide aspects of Knight’s original analysis.

<sup>20</sup> See *infra* Part IV.C.

<sup>21</sup> See *infra* Part III.C.

<sup>22</sup> This means that information that matters very little in most states of the world can become important in a subset of circumstances that may come to pass. The dramatic decline in oil prices, for example, has made bank stakeholders far more sensitive to information about a bank’s loans and other exposures to energy companies. Had oil prices not fallen so dramatically, bank shareholders, creditors and regulators would be far less concerned about this information.

<sup>23</sup> See *infra* Part III.B.

<sup>24</sup> See *infra* Part III.C.

<sup>25</sup> See *infra* Part IV.A.

run and help the market achieve a new equilibrium.<sup>26</sup> Ignorance on the part of market participants creates a friction that impedes the entry of loss-bearing capital where it is needed and the government cannot readily deploy information injections, appropriately priced guarantees, and the other stability-inducing devices when it too lacks high-quality information.<sup>27</sup>

Recognizing and understanding the importance of information gaps sheds new light on the systemic risk arising from shadow banking and the types of reforms required to address it. Most importantly, because complexity increases the pool of potentially pertinent information and the costs of acquiring that information, the analysis provides fresh support for structural reforms that seek to simplify financial instruments and institutions. Additionally, by revealing that information production will inevitably be, and ought to be, incomplete, this Article demonstrates the value of having mechanisms that can ramp up information production in response to early signals of systemic distress.

This Article proceeds in five parts. Part I addresses the differences between equity claims and money claims and the regulatory architecture that traditionally supported the capital markets and banks. Part II introduces the shadow banking system—what it is and why the current regulatory regime is ill suited to support it. Part III explores current understandings of the ways that the distribution of information affects market functioning and the importance of delineating information gaps. Part III also provides a conceptual account of how information gaps contribute to systemic risk and adversely affect the processes required to establish a new and sustainable equilibrium once panic sets in. Part IV draws on critical episodes from the Crisis to establish that the data available is consistent with this Article’s claims regarding the presence of information gaps in the shadow banking system and the tendency of such gaps to increase fragility. Part V addresses implications.

## I. Foundation

This Part lays out, in simplified terms, the differences between money and equity claims and the regulatory regimes that arose to support the issuance and trading of each. In so doing, it synthesizes insights from disparate bodies of scholarship. One byproduct of the historical separation of banking and capital markets is that policymakers, academics and other experts tend to specialize in just one of these two domains. An additional challenge is that in contrast to the relatively robust dialogue between legal academics and financial economists on matters of corporate governance and securities regulation, a similar exchange is only in its infancy in discussions of banking and shadow banking. In distilling key insights from experts in various fields and showing how those insights help to explain the current regulatory architecture, this Part provides the first comprehensive account of how the information-related incentives of money and equity claimants explain key differences in banking and securities regulation.

### A. Equity v. money

A wide variety of financial instruments can be issued to raise capital and money claims and equity claims, in some regards, are merely two ends of a long spectrum. In

---

<sup>26</sup> *Id.*

<sup>27</sup> *Id.*

focusing just on these two types of claims, this Article largely ignores longer term debt and the wide range of other financial instruments that lie between these two extremes, resulting in a stylized account of the markets and regulatory regimes it describes. The nuance lost in this approach is important and additional examination of the markets that lie between these extremes could further illuminate the issues here raised. Nonetheless, even this coarse analysis suffices to establish the core challenges here at issue.

### 1. Equity claims

Equity claims are investments. Persons acquire equity in hopes that the value of the claim they hold will go up and are quite aware of its potential to go down. The expected return on the investment is the reason animating the deployment of capital. Contributing to the information-sensitivity of equity claims is that they are perpetual, meaning that the holder can receive cash in exchange for a claim only by finding a third party willing to acquire the claim. These characteristics, and holders' desire for liquidity, have prompted the creation of secondary markets, many of which are robust and public.

These characteristics contribute to equity markets being information-rich environments. A primary way that investors seek to maximize the probability that their investments will be profitable, and ideally more profitable than other similarly risky investments, is by gathering and analyzing information relevant to the value of claims they might acquire. This does not mean that all investors have or believe they have superior information about the value of claims being traded; there are many noise investors who do not and the presence of such investors is actually critical for enabling more sophisticated investors to profit despite the resources they expend gathering and analyzing information.<sup>28</sup> Nonetheless, informed trading drives equity prices most of the time.

As Ronald Gilson and Reiner Kraakman explain in their work on the mechanisms of market efficiency, in public equity markets, the degree of informational efficiency “depend[s] on the costs of information and the costs of arbitrage—that is, the costs of trading on information.”<sup>29</sup> “The lower the cost of information, the wider its distribution, the more effective the operative efficiency mechanism and, finally, the more efficient the market.”<sup>30</sup> And, because the defining feature of an informationally efficient market is that the price at which a claim is trading conveys meaningful information about

---

<sup>28</sup> Ronald J. Gilson & Reinier H. Kraakman, *The Mechanisms of Market Efficiency*, 70 VA. L. REV. 549, 578 (1984) [hereinafter Gilson & Kraakman, *MOME*] (“It is only because uninformed traders cannot infer *all* information from price—i.e., because prices are “noisy”—that informed traders enjoy a return on their information up to the point at which further trading moves prices beyond the noise threshold.”). *See also* Sanford J. Grossman & Joseph E. Stiglitz, *Information and Competitive Price Systems*, 66 AM. ECON. REV. 246 (1976) (“[I]t is only because prices do not accurately represent the true worth of the securities (i.e., the information of the informed is not fully conveyed through the price system, to the uninformed) that the informed are able to earn a return to compensate them for the costs associated with the acquisition of the information.”).

<sup>29</sup> Ronald J. Gilson & Reinier Kraakman, *Market Efficiency After the Financial Crisis: It's Still a Matter of Information Costs*, 100 VA. L. REV. 313, 330 [hereinafter Gilson & Kraakman, *Information Costs*]. Their work has significant explanatory power across all markets, and actually can help explain many of the features seen in money markets as well. Nonetheless, their framework initially focused on “the relatively well-functioning and continuous markets for public equities.” *Id.* at 330

its relative worth, even a trader that has undertaken no due diligence has high-quality information about the value of claims he is buying or selling.<sup>31</sup>

Critical to the analysis here is that Gilson and Kraakman presume numerous, dispersed traders, often with the aid of reputational and other intermediaries, engaging in ongoing “efforts to acquire additional information, efforts to refine forecasts and deepen the predictive value of information already in hand, and efforts to determine the accuracy of information already in hand.”<sup>32</sup> Traders undertake these efforts, even though they are costly, because they are rewarded for doing so; and, critically, the processes through which they are rewarded are the same mechanisms that enhance price accuracy. These processes are continuous and iterative. Market prices are constantly—and contiguously—moving up and down as traders obtain new information, revise their analyses, and buy or sell in light of that information. As described by economist Bengt Holmstrom, “[e]very piece of information about the value of a firm is relevant for pricing its share,” “[t]his is reflected in the billions of dollars that investment banks and other[s]... spend on learning about firms,” and the result is “[a] continuous flow of information ... into the stock market.”<sup>33</sup>

These characteristics of equity claims also underlie the social functions played by equity markets—facilitating the efficient allocation of capital among competing projects and promoting firm governance.<sup>34</sup> The capacity to produce price signals that compound heterogeneous views on a firm’s prospects is core to the utility of equity markets.

## 2. Money claims

As banking experts have long known and some influential financial economists are starting to highlight, the economics and function of money claims are dramatically different than equity claims. Persons acquire money claims when they place a premium on being able to convert that claim into cash quickly and at par. They are so deploying their capital because they prioritize liquidity and safety over the expected rate of return on that capital.<sup>35</sup>

Money-like claims have two related characteristics that enable them to serve this function—they are very low risk and very short-term. Low risk does not mean no-risk,<sup>36</sup> but a person will only treat a claim like money, rather than an investment, when he

<sup>32</sup> Gilson & Kraakman, *MOME*, *supra* note 28, at 565.

<sup>33</sup> Holmstrom, *supra* note 10, at 7.

<sup>34</sup> E.g., Jeffrey N. Gordon, *The Rise of Independent Directors in the United States, 1950-2005: Of Shareholder Value and Stock Market Prices*, STAN. L. REV. 1465, 1469 [hereinafter Gordon, *Independent Directors*]; Paul Mahoney, *Mandatory Disclosure as a Solution to Agency Problems* 62 U. CHI. L. REV. 1047 (1995).

<sup>35</sup> E.g., Macey, *Reducing Systemic Risk*, *supra* note 10, at 135 (“People who keep their money in MMFs, like those who keep their money in federally insured depository institutions such as commercial banks and credit unions, expect to be able to obtain cash from their funds virtually on demand, and they expect that the value of their investments will not decline in nominal terms.”); Gary B. Gorton, Andrew Metrick & Lei Xie, *The Flight from Maturity* at 10 (NBER Working Paper No. 20027, 2015) *available at* [www.nber.org/papers/w20027](http://www.nber.org/papers/w20027) (explaining that “[m]oney market instruments [that] are not insured... resemble demand deposits” in that they function as a “fairly safe store of value and easy access to the cash because of their short maturities”).

<sup>36</sup> E.g., GARY B. GORTON, MISUNDERSTANDING FINANCIAL CRISES: WHY WE DON’T SEE THEM COMING 19 (2012) (noting that “only the government is able to provide completely riskless collateral”).

expects to be able to exit at par.<sup>37</sup> This is related to the short-term nature of the claims, as the ability to exit, at par, at any sign of trouble—or even an increase in uncertainty—helps to explain why holders treat money claims as virtually risk-free when markets are functioning well.<sup>38</sup> It also means that if a money claimant chooses to exit, it is the issuer rather than the claimant that bears the burden of finding a third party willing to acquire a comparable claim.

Like equity claims, money claims serve a number of socially useful functions, including facilitating transactions and serving as a reliable store of value over time.<sup>39</sup> The important role of such claims is reflected in new evidence suggesting that money claims and other exceptionally low-variance—“safe”—assets have consistently constituted about one-third of all financial assets in the U.S. system since 1952, despite dramatic changes in the size and composition of that system.<sup>40</sup>

One of the greatest differences between money and equity markets relates to the depth and distribution of information among market participants. In particular, while equity markets tend to be information rich, money markets tend to be information sparse. This is in part a byproduct of the structure of money claims. Because money claims are exceptionally short-term, low-variance instruments designed to be redeemable at par, holders have little incentive to generate private information and any effort to do so is quickly cost prohibitive.

The different information dynamics that underlie money and equity markets reflect the fact that these markets often overcome the classic challenge that information asymmetries can inhibit market functioning in quite different ways.<sup>41</sup> Equity markets primarily rely on mechanisms that reduce asymmetries by ensuring all market participants are relatively well informed. Money markets, by contrast, often overcome the challenge of adverse selection through structures predicated on mutual ignorance or by obviating the relevance of private information.<sup>42</sup> Liquidity in both markets thus depends on relative symmetry in the information possessed by both parties, but the information-gathering behavior that is required to support the functioning of equity markets can actually inhibit the functioning of money markets.<sup>43</sup>

As Holmstrom explains, “a state of ‘no questions asked’ is the hallmark of money market liquidity.... this is the way money markets are supposed to look when they are

<sup>38</sup> The omnipresent exit right can also play an important role disciplining issuers of money claims. *E.g.*, Charles Calomiris & Charles M. Kahn, *The Role of Demandable Debt in Structuring Optimal Banking Arrangements*, 81 AM. ECON. REV. 497 (1991).

functioning well.”<sup>44</sup> Economist Gary Gorton and others similarly suggest that the defining characteristic enabling a claim to function as money is that it is effectively “information insensitive.” According Gorton and co-author George Pennacchi, one can define a “liquid security,” the critical feature of a money claim, as one “that it can be traded by uninformed agents, without loss ... to anyone with private information.”<sup>45</sup>

The information-thin nature of money markets is supported and accentuated by the institutions that underlie the production of money claims, just as the institutions that support equity markets promote dissemination and analysis of information. While details vary,<sup>46</sup> these institutions typically incorporate common design features that make it unrewarding or costly for market participants to gather the information about the actual value of the assets underlying a money claim. As Holmstrom explains: “Opacity is a natural feature of money markets.”<sup>47</sup> Focusing on banks, Gorton similarly argues that “[t]he efficient use of bank claims as money entails *eliminating* informative financial markets, so that banks are opaque,” and this is what enables the money claims banks issue to be “accepted at par.”<sup>48</sup> In other work, Holmstrom, Gorton and other co-authors show that debt is the optimal instrument to underlie money claims because it is less sensitive to public or private information than equity.<sup>49</sup>

Another reason money claims are often collateralized by debt is that so long as there is no default on the money claim, accurate information about the value of the underlying debt instrument is not required either when money claim is created or paid off.<sup>50</sup> That the value of assets underlying a money claim never need to be valued precisely, so long as everything goes well, is important is in part because short-term refers to the nature of the commitment that the claimant makes, not the nature of the relationship. Capital often sits in money claims for extended periods. Individuals who place capital into a checking account, for example, may make regular withdrawals, but they often also make countervailing deposits. Similarly, institutional investors who acquire asset-backed commercial paper or provide capital through a sale and repurchase agreement (repo) often roll over those commitments when they nominally mature. This is important to parties on both sides of these relationships. With respect to money claimants, even without due diligence, deciding what type of money claim to acquire entails costs and there can be advantages from holding money claims, so this creates a

slight friction on how quickly a money claimant will decide to walk away. From the perspective of institutions that issue money claims, this is what allows short-term money claims to be used to fund longer term and less liquid assets. The net effect is that money claims can provide a seemingly stable source of financing most of the time. But at no point, even in a long-term relationship, must the holder of the money claim obtain accurate information about the value of the assets underlying that claim.

That money claims can exit quickly and at par underlies the other distinctive feature of money markets—the inherent fragility of any regime that relies on money claims and the potential for widespread withdrawals to lead to value-destroying fire sales and other systemic disruptions.<sup>51</sup> As Diamond and Dybvig showed in the context of banks, coordination problems alone can theoretically explain runs.<sup>52</sup> Because money claims are usually backed by less liquid assets, if a large number of money claimants exercise their right to exit simultaneously—a run—the entity issuing the claims will have to sell assets at distressed fire sale prices, reducing the value of claims not redeemed and giving all claimants an incentive to be first in line if they expect widespread withdrawals.<sup>53</sup>

This inherent fragility of money markets and the externalities that arise when money claimants run help explain why most banking systems are heavily regulated, as governments often feel compelled to provide support during crisis periods regardless of whether they have limited risk taking or imposed other regulations *ex ante*. At the same time, runs are the aberration, not the norm. The informational dynamics highlighted here shed light on the when and why of runs and can provide an information-based explanation for specific runs that have, perhaps incorrectly, been characterized as “sunspots” brought about by coordination problems.<sup>54</sup>

That money claimants prioritize certainty while equity holders seek to maximize their risk-adjusted returns does not mean that either group is indifferent to other attributes of the claims that they hold. Equity holders also value liquidity and, holding all else equal, money claimants prefer a slightly higher rate of return.<sup>55</sup> Nonetheless, as reflected in the growth of funds that limit exit rights, equity claimants are often willing to forego liquidity in exchange for a higher expected rate of return. Similarly, any variation in other terms of money claims are always constrained by the overarching requirement that the claims be so low risk and short-term that most information would not affect the value of the claim.

This brief summary of the differences between equity and money markets is descriptive, not normative. Just because adverse selection can be overcome either through mechanisms that level up or level down the informational playing field does not imply equivalence between the two approaches. Each has distinct advantages and drawbacks.<sup>56</sup>

## B. Two sustainable systems: securities v. banking regulation

Between the Depression and the Crisis, financial markets in the United States were remarkably stable and well-functioning.<sup>57</sup> The banking system and the capital markets each suffered some setbacks, and banking and securities laws were revised accordingly, but there were no major crises. As this subpart shows, one reason for this stability is that the regulatory regime governing each domain was well suited to support the distinct informational needs and incentives of the persons providing the capital that supported the regime: securities laws were suited to support equity markets, as equity was the paradigmatic claim traded in the capital markets, and banking law addressed the distinct needs of money claimants who provide the bulk of capital on which banks rely.<sup>58</sup>

### 1. Securities regulation

At the heart of U.S. securities regulation is a set of mandatory disclosure obligations. Any firm that raises capital from the public must commit to provide, on an ongoing basis, detailed information about the firm's operations and financial health.<sup>59</sup> By making it easier for investors to obtain timely information about a firm's performance and prospects, and by requiring that such information be provided in a standardized form, these requirements promote informational efficiency by reducing the costs that investors incur to obtain and analyze pertinent information.<sup>60</sup>

These mandatory disclosure obligations are buttressed by rules that impose liability for noncompliance and prohibit fraud and manipulation.<sup>61</sup> By reducing the costs investors would otherwise incur verifying the accuracy and completeness of the information so disclosed, these regulations further facilitate the dissemination of information and promote informed trading.<sup>62</sup> A third component of U.S. securities

Coffee, Jr., *Market Failure and the Economic Case for a Mandatory Disclosure System*, 70 VA. L. regulation prohibits insider trading, limiting the ability of management to profit from their superior access to information.<sup>63</sup> Even these rules may support the processes through which share prices come to contain information about a firm's relative value.<sup>64</sup>

In contrast to many of the state securities law regimes in place prior to the federalization of the securities laws in the early 1930s, the federal regime does not ask, or even allow, regulators to make any substantive judgments about the value of claims issued.<sup>65</sup> The role of securities regulators, instead, is to promulgate and enforce rules that ensure investors have access to timely and accurate information.<sup>66</sup> As John Coffee and Hillary Sale have explained: “By culture and philosophy, the SEC is a disclosure regulator, whose concerns with risk and leverage are normally satisfied once full disclosure is made.”<sup>67</sup>

There has been debate about the need for law to play the roles that it currently does facilitating information dissemination, but even those who question mandatory disclosure typically do so on the basis that private institutions would suffice to ensure that information is disclosed and compounded into share price.<sup>68</sup> That share prices contain information about the value of the claims traded and that it is market participants, not regulators, who make the substantive assessments about the value of those claims is widely assumed and expected. This assumption marries well with the nature of equity claims—by giving holders significant downside and unlimited upside, holders of equity claims can enhance their expected returns by generating superior information about the value of those claims. Equity claimants are thus strongly incentivized to engage in information gathering and analysis, and would be irrespective of the regulatory regime. The regulatory regime works because it harnesses and facilitates the pre-existing incentives of equity claimants.

The net effect of the private and public forces at work in equity markets is that at any point in time, the price at which an equity claim is trading contains significant information about its value relative to other claims. This is why equity markets are often characterized as being informationally efficient, at least on a relative basis, most of the time.<sup>69</sup> One ramification of this combination of complementary institutions is that even an investor who does not undertake any due diligence to rely on the price to aggregate

the different views of disparate, sophisticated traders about a firm's expected performance and other factors that could affect share value. Collectively, market structure and regulation work thus together to facilitate a range of processes that encourage sophisticated investors to gather and analyze information and enable other investors to piggyback on the hard work of the sophisticates.

## 2. Bank regulation

Bank regulation rests on an entirely different set of premises than securities regulation and is undertaken by an entirely distinct group of regulators. Whereas the Securities and Exchange Commission (SEC) and the Commodities Futures Trading Commission have primary responsibility for ensuring the integrity and functioning of the capital markets, the Federal Reserve, the Office of the Comptroller of the Currency, and the Federal Deposit Insurance Corporation (FDIC) are the bank regulators in the United States. While securities regulators are stereotyped as always favoring more disclosure and strong enforcement, bank regulators are stereotyped as always leaning toward confidentiality and under-enforcement.<sup>70</sup> Bank regulators are also regularly required to make the type of substantive, judgment-laden decisions that the securities regulatory regime allocates exclusively to market participants.

Banking is among the most heavily regulated activities in which a firm can engage.<sup>71</sup> To become a bank, a firm must undergo an intensive chartering process.<sup>72</sup> Thereafter, banks are subject to significant limitations on the types of activities in which they can engage and the types of assets they can hold. Traditionally, these restrictions both limited the risks that banks could assume and facilitated the ability of bank supervisors to understand those risks.<sup>73</sup> All banks and bank holding companies are also subject to an extensive oversight regime. As reflected in the lengthy supervisory manuals issued by each of the bank regulators, bank examiners regularly undertake a close examination of virtually every aspect of a bank's operations.<sup>74</sup> These processes provide bank regulators with a comprehensive picture of a bank's operations and risk exposures.<sup>75</sup> Bank regulators also have authority to address any deficiencies they detect during the examination process. If a bank violates a statute or regulation or is engaged in other activities that threaten the bank's safety and soundness, bank regulators can obtain a

cease and desist order, impose civil monetary penalties, have employees and other affiliates removed, and take other enforcement actions to address the issue.<sup>76</sup>

Also critical to this regime is the ability of bank regulators to close a financially distressed bank.<sup>77</sup> Bank regulators need not wait for a bank to be insolvent or unable to pay its debts to force a bank into receivership. Rather, they can close a bank on a range of bases that suggest a bank is unlikely to regain its health.<sup>78</sup> This regime gives bank regulators significant authority to intervene if a bank does get into trouble and further buttresses their authority to extract useful information in connection with their examinations. Moreover, if a bank's primary regulator determines the bank should be closed, a bank regulator—the FDIC—controls the receivership process.<sup>79</sup> Overall, “[t]he FDIC enjoys a level of control that a dominant creditor could only dream of obtaining in bankruptcy.”<sup>80</sup>

The scope of this regime can largely be explained by the incentives of money claimants and the systemic ramifications of banking panics. The massive regulatory regime governing banks makes it easier for the money claimants who provide the great bulk of a bank's capital to remain only minimally informed. This is in part because the government's ongoing oversight reduces the need for depositors to engage in comparable monitoring. Just as importantly, oversight enables widespread deposit insurance, which significantly curtails the downside risks to which most money claimants are exposed and makes them less likely to run.<sup>81</sup> These programs benefit depositors, who are now freed from having to engage in costly diligence, but they also benefit society more generally by reducing depositors' incentive to run, thus making a banking crisis less likely.

The extensive regulatory regime governing banks also facilitates the government's ability to respond appropriately during periods of systemic distress. For example, to further discourage depositors from panicking and to reduce the adverse consequences if they do, qualified banks can readily access fresh liquidity from the Federal Reserve's discount window. By conditioning access to its primary discount window on a bank's confidential, supervisory rating, the Federal Reserve reduces the moral hazard that arises from such access and the credit risk to which it is exposed.<sup>82</sup> Similarly, if bank assets prove insufficient to justify the amount of information insensitive capital on which they had come to rely—that is, if the banking system is inadequately capitalized—the information produced by the oversight regime can provide policymakers information about the costs and risks of closing or recapitalizing troubled institutions.

<sup>82</sup> 12 C.F.R. § 201 (2009). See *infra* fn 86 and accompanying text on the opacity of banks.

To be sure, banks also rely on non-money claims to fund their operations. Holders of equity and subordinated debt a bank issues, as well as a bank’s other creditors, impose important market discipline, and there are informational benefits to regulatory strategies that require a bank to increase such capital cushions.<sup>83</sup> Banks are also subject to numerous disclosure requirements.<sup>84</sup> Nonetheless, banks are more opaque than other firms and disclosure requirements have lagged far behind the changing nature of banking.<sup>85</sup> The banking system historically may thus be understood as a regime that limits the degree of information production that the providers of capital need to undertake and the limited private information production counterbalances with a supervisory regime that provides bank regulators detailed information about, and control over, bank activities.

The assurances that the government provides to persons holding money claims issued by banks are not costless. Deposit insurance and implicit guarantees give rise to moral hazard, reduce market-based discipline, and can result in significant government liabilities.<sup>86</sup> There are also fewer mechanisms for checking errors and protecting against biases and capture than in a market-based regime.<sup>87</sup>

At the same time, the inherent fragility of any intermediation regime that issues money claims and the externalities that arise when those fragilities become manifest are important considerations when assessing the moral hazard and other drawbacks of regulating banks so extensively. That runs by money claimants can have significant adverse effects on the real economy curtails the capacity of the government to credibly commit that they will not intervene to help stop runs even without ex ante regulation. As reflected in the debates over too-big-to fail, failing to regulate does not eliminate moral hazard and can create other challenges.<sup>88</sup> The aforescribed banking regulatory regime that limited the creation of banks, imposed significant restrictions on them, and created a

large body of regulators charged with monitoring bank activity was quite stable for a remarkable length of time.<sup>89</sup>

The aim here is not to provide an exhaustive account of bank regulation or securities regulation, but rather to highlight how key differences in the two regimes can be explained by the different information-related incentives of the critical providers of capital. In the capital markets, regulators' primary role is to promote relative efficiency and facilitate effective governance by reducing the costs that market participants incur gathering pertinent information. At no time are regulators making any substantive assessments regarding the business models of the firms raising capital or the value of the equity claims they issue. By contrast, it is the role of bank regulators to gather significant information about banks' assets and activities and exercise judgment with respect to the riskiness of the activities and value of those assets. Historically, bank regulators were aided in these undertakings by rules that limited bank activities and investments to ones regulators could readily understand.<sup>90</sup>

Juxtaposing these regimes also brings to the fore differences in the relationship between when information is produced in each regime and when, if ever, that information that becomes public. In both domains, information about the value of firm assets and expected future performance is constantly produced by persons who can discipline firms in light of what they learn. In public equity markets, this is an entirely public process, as the purchases and sales that discipline a firm simultaneously move its share price. By contrast, bank regulation occurs largely behind a shroud of confidentiality. Bank regulators regularly assess multiple dimensions of each bank's operations and issue supervisory letters identifying areas for improvement, but all of this information remains confidential, typically indefinitely.<sup>91</sup> This, again, is consistent with the notion that prudential regulation seeks to obviate the need for smaller money claimants to have any information about the actual value of the assets underlying their claims while securities regulation encourages and facilitates the very due diligence and valuation efforts banking regulation discourages.

## II. Shadow Banking

### A. The rise

The dramatic differences between the banking system and the capital markets mattered little historically because each regime operated largely independent of the other. This started to change in the 1970s with the rise of an array of market-based mechanisms that collectively fulfill many of the economic functions long performed by banks. Today these mechanisms are known as the shadow banking system. In stark contrast to banks, which undertake the full amount of liquidity and maturity transformation within individual institutions, the shadow banking system accomplishes these undertakings through a series of interrelated market transactions and structures which are often

<sup>91</sup> *Id.* at 442 (explaining that “examination reports and examiners’ workpapers remain confidential”).

consummated at different points in time even though reliant on the others.<sup>92</sup> The institutions that issue money claims are just a subset of these arrangements.<sup>93</sup> Nonetheless, the money claims issued by the shadow banking system are critical, as the functioning of the overall system depends on capital that flows through money claims.<sup>94</sup> As the Crisis revealed all too vividly, when money claimants make large-scale withdrawals from shadow banks, the effects are felt throughout the shadow banking system and widespread market dysfunction often follows.<sup>95</sup>

That the Crisis emanated from the shadow banking system and revealed the money claims issued in that system to be less safe than many holders previously believed did cause the system to contract.<sup>96</sup> Yet this contraction proved short lived. The shadow banking system has since re-established its pre-Crisis size and is poised for further growth.<sup>97</sup> According to one measure, the size of the worldwide shadow banking system currently stands at \$75 trillion.<sup>98</sup> The rapid growth of the shadow banking system has been particularly pronounced in the United States, the only country where the shadow banking system is larger than the regulated banking sector.<sup>99</sup>

The importance of the shadow banking system in the United States is reflected in the declining importance of regulated banks. In 1970, commercial banks, savings institutions, and credit unions collectively held 54.41% of the assets in the financial sector, roughly the same amount they had held a decade earlier.<sup>100</sup> That figure fell to just 24.22% by 2005.<sup>101</sup> Other metrics tell a similar story. For example, in 1980, banks provided the great bulk of the capital used to fund home loans; by 1990, market-based sources of capital (i.e., shadow banking) had roughly caught up with banks; and, by 2009, the value of homes loans financed through the capital markets was more than twice the value of home loans financed by banks.<sup>102</sup> These figures may overstate the decline of

banks, as implicit and explicit guarantees from banks played a critical role supporting the shadow banking system, but they accurately convey how shadow banks are overtaking banks as providers of money claims and providers of capital for productive undertakings.<sup>103</sup>

The reasons for this growth remain incompletely understood.<sup>104</sup> It is clear that this system could not exist but for an array of legal and financial innovations that enabled new methods of pooling and the issuance of new types of financial claims. Given the economic equivalence between much of what the shadow banking system accomplishes and the functions long served by the banking system, regulatory arbitrage is clearly among the driving forces. Yet, there are also indicia that the system has grown in part to satisfy demands that the banking system cannot address.<sup>105</sup> In particular, recent empirical work shows a strong demand for money claims in amounts that the banking system cannot readily produce.<sup>106</sup> Apple, Inc., for example, currently has \$203 billion in “cash equivalents” that it needs to park somewhere.<sup>107</sup> Particularly in an era in which policymakers are seeking to ensure that no bank is “too big to fail,” banks are not suited to produce money claims in the amounts required to satisfy the needs of Apple, other large firms, and institutional investors. Recent work by Zoltan Pozsar shows how the global savings glut, whereby U.S. Treasuries and similar assets are in short supply in the United States because of foreign demand for such assets, coupled with the increasingly sophisticated cash management systems used by firms and institutional investors is contributing to the mismatch between the demand for safe assets like money claims and assets that are inherently safe without the credit enhancement devices used in shadow banking.<sup>108</sup> In short, while still incompletely understood, the shadow banking system appears to be playing important economic functions in today’s financial system, including a number that could not readily be satisfied in other ways.

## B. Information in the shadow banking system

### 1. Money claims

One way the shadow banking system resembles the banking system is that much of the capital flowing into the regime—while subsequently channeled through layers of complex arrangements—enters via the issuance of money claims.<sup>109</sup> The money claims

issued in the shadow banking system share the same general characteristics of all money claims described above—they are structured to be sufficiently low-risk and short-term that holders need not engage in meaningful due diligence. They are also akin to the money claims issued by banks in that the assets backing the claims are longer term, less liquid investments, and the claims are structured to obviate the need for the parties to agree on the value of the underlying assets at any stage in the relationship.

Often, but far from always, money market mutual funds intermediate the creation of money claims in the shadow banking system. Money market mutual funds, which first appeared in the United States in 1970, held total assets of approximately \$3.8 trillion by 2008.<sup>110</sup> Unlike most mutual funds, money market mutual funds are subject to stringent regulatory restrictions on the types of assets they can hold, many of which are themselves money claims.<sup>111</sup> In exchange for abiding by these restrictions, money market mutual funds traditionally were allowed to report a share price of exactly \$1.00 under most circumstances.<sup>112</sup> This regime intentionally reduced price accuracy, yet it worked remarkably well for an extended period of time. Prior to the Crisis, only one money market mutual fund, and a small one at that, had ever redeemed shares at less than \$1.00 per share.<sup>113</sup>

Looking past and within money market mutual funds reveals other institutional arrangements that enable the creation of money claims outside of banks. Overcollateralization, the use of highly rated (and often securitized) assets as collateral, and backup commitments from issuers and sponsors are all devices deployed—often in conjunction with one another—to assure money claimants that that the issuer would be able to redeem their claims at par. One reason that these devices are so useful is that they expand, significantly, the capacity of the non-bank financial system to issue claims that are insensitive to most information.

Asset-backed commercial paper (ABCP), a common type of money claim pre-Crisis, illustrates how this works. A common structure for creating ABCP started with a bank or other type of financial institution creating a bankruptcy-remote entity. That entity would hold relatively long term and often securitized assets, like mortgage-backed securities and collateralized loan obligations, which would be funded through the issuance of ABCP, which typically had very short maturities and some longer term securities.<sup>114</sup>

ASHCRAFT, FED. RESERVE BANK N.Y. STAFF REPORT NO. 580, SHADOW BANKING: A REVIEW OF THE LITERATURE 6 (2012) (“The maturity of ABCP is between one and 180 days.”). Just as in the banking system, the need for information-sensitive, loss-bearing capital to support the issuance of money claims creates a friction on the rate of money creation and results in some information production, but that alone does not suffice for stability.

This arrangement was often supported by explicit or implicit commitments by the sponsoring bank to provide the entity liquidity support if needed and sometimes there was also an expectation that the sponsor would provide credit support if required to protect the value of the ABCP issued.<sup>115</sup> The holders of the ABCP issued were not entirely ignorant; they were not willing to acquire the ABCP without meaningful assurances that it was exceptionally low risk. Yet the information they relied on to make that determination, such as the credit ratings of the securitized assets held by the issuing entity and the degree of over-collateralization, were proxies that are probative but imperfect indicators of credit risk. The costs of acquiring more accurate, first-hand information about the value of the assets underlying their claims was prohibitively expensive in light of the nature of the claims they were holding.<sup>116</sup> That holders were only minimally informed does not mean that they were naïve or dumb. They were willing to rely on probative but imperfect proxies of actual credit risk because they enjoy the other privilege that holders of money claims always enjoy—the ability to walk away at par.

Just as in the banking system, the capacity of the persons supplying capital to walk away, quickly, at any sign of trouble is a mixed blessing. The short-term nature of the commitment enables a distinct form of discipline, one that is sometimes optimal.<sup>117</sup> And, like the free banking era, the vibrancy of the shadow banking system attests to the capacity of a wholly private regime to create viable money claims.<sup>118</sup> Yet, one reason that banks are now so heavily regulated is that the incentives of individual money claimants often deviate substantially from those that are socially optimal. The same walk-away rights that enable money claimants to rationally remain only minimally informed simultaneously render any system that relies heavily on money claims inherently fragile. And when money claimants exercise their exit rights en masse, value-destroying fire sales and other adverse systemic repercussions often follow.

## 2. Beyond money claims

A brief look at how the capital flowing through money claims funded longer term projects brings into relief the distinct information dynamics at play in the shadow banking system. Recall, in the banking system, liquidity transformation and maturity transformation occur entirely within a single firm. In contrast, shadow banking achieves that same degree of liquidity and maturity transformation but through multiple layers of interconnected, market-based structures. Starting with the description just provided, money market mutual funds would obtain capital by issuing shares. The money market mutual fund would then acquire ABCP and other financial claims that are sufficiently short-term and sufficiently safe that they often are themselves money claims, and that capital in turn would enable the issuing entity to hold ABS. Those ABS are, in turn, the

product of a securitization transaction that enabled the capital from various tranches of ABS issued to be used to acquire underlying credit instruments.

ABCP conduits and ABS structures are both examples of fragmentation nodes.<sup>119</sup> Fragmentation nodes are structures that bundle financial claims, such as home loans or securitized assets, together and then divvy out rights to the cash flows from those assets to various classes of claimholders.<sup>120</sup> Fragmentation nodes are critical to shadow banking as these structures enable the inherently risky and longer term loans that borrowers require to be funded by capital from persons seeking claims that have shorter maturities and are far less information sensitive. Such transformation is possible; there is no voodoo required. So long as the underlying assets are genuinely diverse and their performance is imperfectly correlated, pooling those assets and issuing different tranches of claims enables meaningful credit transformation, and can also facilitate liquidity and maturity transformation. The dramatic rise of fragmentation nodes as pervasive features in today's financial landscape can be attributed, at least in part, to the way such structures enable risks to be redistributed among different classes of holders in accordance with their relative capacity to bear particular risks.

At the same time, the spread of fragmentation nodes and the other types of support mechanisms that enable the issuance of money claims in the shadow banking system dramatically increase the range of information potentially pertinent to the value of the financial claims created in that system and the health of the financial institutions operating within it. The value of an ABS, for example, depends not only on the quality of the underlying loans, but also on factors that are specific to the securitization structure issuing that ABS, such as the correlation among the underlying assets and the contractual terms determining how interest and principal paid on the underlying assets will be allocated to the various classes of securities issued.<sup>121</sup> Prior to the creation of the securitization structure, these were not pertinent to anyone.<sup>122</sup> The relationship between degree of correlation among the underlying assets and the value of a newly created ABS also varies significantly across the different "tranches" of ABS issued. As a result, the interests of the investors who acquire the lower rated tranches, which are information sensitive, do not align with the interests of the holders of the AAA tranche that typically backed money claims.<sup>123</sup> That the expected return on the underlying assets may be more correlated than assumed in the model used to create the securitization structure, for example, is information that would adversely affect the values of the AAA-tranche while increasing the value of the lowest tranches. This is an example of information that no one involved had both the incentive and means to produce at the time a securitization transaction was consummated. It also explains why the presence of some informed, loss-

<sup>121</sup> For a more thorough explanation of these dynamics, *see id.* at 678–81.

<sup>122</sup> To be sure, the correlation between the expected performance of a mortgage and the expected performance of the overall market mattered with respect to the pricing of that mortgage, and if, as was sometimes but not always the case, the mortgages packaged into a securitization structure were all originated by the same bank, then that bank would care about the correlation among their expected returns. In each instance, however, the reference group would be a much larger and more diverse group of assets. The importance of the correlation among the specific mortgages placed together into a securitization structure is contingent on the creation of that structure.

<sup>123</sup> *Id.*

bearing capital in the shadow banking system does not suffice to counteract the ignorance of money claimants.

ABCP programs and many of the other entities that issue money claims are also fragmentation nodes. They similarly bundle together assets that previously had no connection to one another and issue claims that have different rights with respect to the cash flows from the underlying assets. As with ABS, the process of creating such fragmentation nodes can create value by facilitating liquidity and maturity transformation. But, again, it is a process that makes factors that were once not relevant to anyone or anything, like the correlation among the underlying assets and the circumstances in which the sponsoring bank will provide support to the program, highly pertinent to the value of the ABCP and other instruments created to fund the program.

These information dynamics and the structure of ABCP programs also demonstrate the ways complexity and ignorance may sometimes promote market functioning. For the reasons just described, the securitized assets underlying the ABCP were often exceptionally complex.<sup>124</sup> The complexity of the assets underlying many ABCP programs not only made it uneconomical for the ABCP holders to engage in the due diligence required to produce private information about the value of those assets, it also made it exceptionally costly for the sponsoring banks to produce such information. This likely helped convince ABCP holders that the sponsoring bank had not undertaken those efforts and thus did not have superior information about the quality of the assets that it could use to the detriment of the ABCP holders.<sup>125</sup> The complexity thus may have enhanced the capacity of the ABCP issued to operate like money by reducing the probability of adverse selection.<sup>126</sup>

### C. Information gaps

Juxtaposing this brief glimpse of the money markets that feed the shadow banking system and the plumbing that enables that system to create money claims with the regulatory architecture set forth in Part I reveals a core informational challenge. Because the shadow banking system operates in the capital markets, to the extent these activities are regulated at all, the default rules governing their operation come from securities regulation. The default regulatory regime is thus one that presupposes claimants who are incentivized to engage in meaningful information gathering and analysis.<sup>127</sup> The market and payoff structures for money claims, however, provide no reward for acquiring superior information. Like bank deposits, the money claims produced by shadow banks are structured to obviate the need for the holder to have high-quality information about the value of the underlying assets at any stage in the relationship. By examining the incentives of the persons providing a significant swathe of the capital flowing into the

<sup>124</sup> See, e.g., GORTON, MISUNDERSTANDING FINANCIAL CRISES, *supra* note 36, at 50 (“The structure of asset-backed securities can be very complicated and opaque. The idea is that they make good collateral because of their lack of secrets.”).

<sup>126</sup> *Id.*

<sup>127</sup> To be clear, much shadow banking falls into exemptions built into the securities laws, but the need to fit into those exemptions is an important way that securities laws affect shadow banking, and the contours of those exemptions can be explained in much the same terms as the rationales for the overall regime.

shadow banking system and the structures that populate that system against the default regulatory regime governing this system, this analysis reveals that there are structural reasons to expect significant information gaps in the shadow banking system.

The shadow banking system enables the growth of large information gaps, in part, because the value of the information that resides in those gaps varies significantly in different states of the world. The identified information gaps typically have little adverse impact on market functioning so long as confidence reigns—and may even facilitate it—but the ramifications of these gaps change precipitously if that confidence begins to wane.<sup>128</sup> Post-crisis reforms have mitigated, but are far from eliminating, these dynamics.<sup>129</sup>

Another insight that arises from examining shadow banking against the background regulatory architecture and the information-related incentives of the providers of capital is that there may be structural reasons to expect far greater complexity in the shadow banking system than in either banks or the capital markets as historically constituted. A core component of traditional bank regulation entailed limitations on banks' activities and investments. The complexity-limiting effect of these regulations was a critical component enabling bank regulators to understand the risks to which banks were exposed. Similarly, a sophisticated investor acquiring a financial claim as an investment will typically be wary of any product that is too complex for him to understand, which traditionally limited the complexity of instruments trading in the capital markets. As a result, the regulatory and market forces that ensured someone had high-quality information about the value of assets and their associated risks simultaneously operated to limit the complexity of the instruments created. These limitations were never perfect and they appear to have become potentially much weaker over time,<sup>130</sup> yet shadow banks operate in an entirely different paradigm. In the shadow banking system, even under normal circumstances, there are often few or no market-based or regulatory forces limiting the complexity of the claims created, and that complexity may even facilitate liquidity in some states of the world. This is relevant to the analysis here, as the degree of complexity directly affects the size of information gaps that are likely to arise and the cost of filling those gaps should subsequent events require them to be filled.<sup>131</sup>

### III. The New Informational Challenge

Framed in terms of information, the existing regulatory apparatus was designed to support two distinct regimes: (1) a banking system that enables most providers of capital to remain minimally informed and mitigates the associated systemic risk and potential moral hazard through a massive regulatory regime; and (2) a capital markets regime that relies on capital providers who are incentivized to gather and analyze information wherein the primary role of regulation is to reduce the costs of those efforts. The shadow banking system does not fit either paradigm.

This mismatch and the information gaps that arise from this mismatch give rise to a range of policy issues. The remainder of the analysis will focus on an important subset of those issues—how the information gaps that arise from shadow banking affect fragility. This Part explains the shortcoming in existing frames for analyzing the production and distribution of information that is filled by identifying information gaps. It then explores the relationship between information and market functioning before developing this Article’s claim—that information gaps directly contribute to the systemic risk arising from shadow banking. Part IV tests this claim against evidence from the Crisis.

#### A. Information gaps in context

Economists and other experts have long recognized that information and lack of information can have profound implications for market functioning. Much of the analysis thus far rests upon the rich literature addressing these dynamics. To grossly oversimplify, that literature tends to operate within one of the frameworks: one focused on how information is distributed within a system and a second focusing on the nature of information that is missing.

Current understandings of the importance of how information is distributed among parties often build on George Akerlof’s insight that when information is distributed asymmetrically and buyers rely on “some market statistic to judge the quality of prospective purchases,” “there is an incentive for sellers to market poor quality merchandise.”<sup>132</sup> Buyers, anticipating this adverse selection, discount what they are willing to pay accordingly, with the net result that no trade will take place even when an exchange would be welfare enhancing.<sup>133</sup>

Other scholars have shown that modest asymmetries in how information is distributed among parties can positively impact market functioning. A central insight in Gilson and Kraakman’s original analysis of the mechanisms of market efficiency is that it is only when “prices do not disclose all information,” that there can “be an ‘equilibrium degree of disequilibrium’ somewhere short of full efficiency” that enables sophisticated investors to profit from engaging in costly information gathering and analysis even in relatively efficient capital markets.<sup>134</sup> John Coffee’s work on gatekeepers, such as accountants and credit rating agencies, similarly reveals how the ability for such parties to profit from superior information about the financial health or other characteristics of an issuer plays a critical role compensating them for the costly effort of producing that information.<sup>135</sup> Much of the literature explaining the rationales for mandating disclosure in securities markets and prohibiting activities like insider trading similarly shed light on how the distribution of information affects market functioning, and how market structure

and other institutional arrangements can promote and blunt incentives to produce information that is disaggregated or otherwise not yet known.<sup>136</sup>

A separate vein in the literature on how incomplete information affects financial and other decision-making shifts the focus from how information is dispersed among parties within the system to the nature of information that is missing. Much of this work builds on the risk-uncertainty dichotomy first articulated by Frank Knight nearly a century ago.<sup>137</sup> As Knight explains, “[t]he ... difference between the two categories, risk and uncertainty, is that in the former, the distribution of the outcome in a group of instances is known (either through calculation *a priori* or from statistics of past experience).”<sup>138</sup> By contrast, “true uncertainty” is “not susceptible to measurement.”<sup>139</sup> This distinction has profound implications for decision-making. As Knight further explained, unknowns that represent risks can be “converted to effective certainty” by insurance and similar schemes that group similar instances together and enable individuals to pay a risk-adjusted fee to mitigate adverse outcomes.<sup>140</sup> The same mechanisms are not available to mitigate the effects of unknown unknowns.

While Knight assumed markets to be more complete than they are, his core insight remains relevant and influential. Economists and others regularly invoke the notion of Knightian uncertainty as a way of acknowledging the inevitability of unknowable unknowns.<sup>141</sup> There is now a rich body of literature, much of it building off of a thought experiment by Daniel Ellsberg, examining how uncertainty affects decision making, which establishes that individuals tend to be “ambiguity averse,” and explores the ramifications of that tendency in an array of settings.<sup>142</sup> A number of efforts to better understand the causes of the Crisis similarly identify uncertainty as a significant factor contributing to its depth.<sup>143</sup>

<sup>138</sup> *Id.* at 233.

<sup>139</sup> *Id.* at 232.

<sup>140</sup> *Id.* at 46.

<sup>141</sup> Knight recognizes that because of uniqueness, there is some irreducible uncertainty, but his analysis is largely framed by reference to a particular market actor, and his initial framing treats risk as a changing subset of uncertainty. See KNIGHT, *supra* note 19, at 233–63. For further discussion on gaps between Knight’s original analysis and ways the notion of Knightian uncertainty are typically employed, see, e.g., Geoffrey T.F. Brooke, *Uncertainty, Profit and Entrepreneurial Action: Frank Knight’s Contribution Reconsidered*, 32 J. HIST. ECON. THOUGHT 221 (2010); Stephen F. Leroy & Larry D. Singell, *Knight on Risk and Uncertainty*, 95 J. POL. ECON. 394 (1987). Itzhak Gilboa et al., *Probability and Uncertainty in Economic Modeling*, 22 J. ECON. PERS. 173 (2008). Formal analyses of contracting and other forms of decisionmaking have found ways to minimize the importance of Knightian uncertainty by introduction the notion of “subjective probability,”<sup>142</sup> See generally Talley, *supra* note 19, at 763–71 (citing Daniel Ellsberg, *Risk, Ambiguity, and the Savage Axioms*, 75 Q.J. ECON. 643 (1961)) (providing an overview of this literature and Ellsberg’s influence).

<sup>143</sup> See, e.g., Katharina Pistor, *The Legal Theory of Finance*, 41 J. COMP. ECON., 315, 318 (2013). (“pre-determined, binding, non-negotiable legal commitments can hasten a financial crisis and in the extreme case the financial system’s demise”). Ricardo J. Caballero & Arvind Krishnamurthy, *Collective Risk Management in a Flight to Quality Episode*, 63 J. Fin. 2195, 2197 (2008) (examining how an increase in uncertainty can generate flight to quality effects); Viral V. Acharya, Douglas Gale & Tanju Yorulmazer, *Rollover Risk and Market Freezes* 5 (Nat’l Bureau of Econ. Research, Working Paper No. 15674, 2009) (providing an account of market freezes that depends, in part, on “uncertainty about credit risk of the underlying asset ... not be[ing] fully revealed by the date of next rollover”)

Each of these frames and other bodies of inquiry that have evolved alongside them enhance our ability to understand the dynamics here at issue, yet none provide an easy way to delineate situations where the relevant information is theoretically knowable or otherwise conducive to measurement but not actually known by any party. Implicit in the notion of an information asymmetry is that *someone* has the information. Information asymmetries can impede market functioning if the probability of adverse selection is too great, but trading on superior information is how private market actors profit from that information. Thus, so long as someone has the information, that information will usually be revealed, even if indirectly, and the market will move toward a new equilibrium that incorporates that information.

The situation changes significantly when pertinent information is not fully known to any party in the system. Market participants must make a threshold determination of whether to engage in the requisite data gathering and analyzing before they can engage in informed trading. The higher the costs the less often it will be rational for them to incur these threshold expenses.<sup>144</sup> The government similarly cannot make credible signals about information it lacks and it cannot accurately price insurance-like information substitutes.<sup>145</sup> Situations where no party has pertinent information thus pose challenges that are different in kind than the ones that arise when information is asymmetrically distributed among market participants or regulators.

When no party has relevant information, the gap that results operates like an unknown unknown. Information gaps thus increase the effective uncertainty in any system. Yet these gaps do not fit neatly into the dichotomy promulgated by Knight. Knightian uncertainty is generally an exogenous variable outside of anyone's capacity to control. By contrast, when pertinent information is knowable but lacking, policymakers and market participants can undertake activities that reduce those gaps. Delineating situations where missing information is knowable from other types of uncertainty is thus a critical threshold step to understanding the private and public mechanisms available when the challenge is one of unknowns.

One reason for this conceptual gap and the minimal attention that has been paid to information that is knowable but unknown may be that information gaps can only be identified through structural analyses of the type performed in Parts I and II. Analyses that focus on the parties to a transaction—the focal point of most studies of financial and other forms of contracting—or that examine the nature of pertinent but missing information are never going to identify this type of information dynamic. Accentuating the challenge is that this type of structural analysis will typically be an inductive exercise that requires probabilistic inferences. It is rarely possible to establish with certitude that particular information was not actually known to any party, private or public, at any juncture in a large and complex intermediation regime. This does not mean empirical evidence is irrelevant. Part IV undertakes a close analysis of how this Article's claims regarding the existence of information gaps and their effects on market functioning comport with the data available about how market participants actually behaved at critical points during the Crisis. Nonetheless, these challenges help to explain why this

important category of information dynamics has not been identified and examined more closely until now.

## B. Incomplete information and market functioning

To understand why information gaps matter, it is helpful to review what we already know about the relationship between information and market functioning. As reflected in the disparate assumptions animating securities and bank regulation, however, there is no universal “we” in this space. This subpart, accordingly, creates the required common ground. It identifies four core understandings that build upon one another and lay the foundation for this Article’s contributions regarding the importance of information gaps.

A threshold issue, which is often misunderstood, is that lack of information does not necessarily impose any friction on market functioning. The difference between situations where lack of information will preclude market functioning and where it will not is illustrated by Akerlof’s famous used car market. The reason Akerlof focused on used cars—rather than new cars—is that even though the cars for sale in *both* markets entail a mix of cherries and lemons, a dealer selling new cars is not assumed to possess private information about the categorization of any particular vehicle.<sup>146</sup> In Akerlof’s analysis, whether a car is a lemon could be known only with extended use.<sup>147</sup> And so long as a new car dealer does not possess superior information about whether a vehicle is a lemon, he has no ability to discriminate on that basis.

When information is lacking, rather than asymmetrically distributed, both the buyer and seller can use probabilistic estimates to gauge the likelihood that a particular vehicle is a lemon, and both can discount the expected value of a vehicle accordingly.<sup>148</sup> Ex post, the utility that the buyer enjoys will depend on whether he receives a lemon or cherry, but that fact should not inhibit the transfer.<sup>149</sup> While a stylized car market is quite different from today’s financial markets, this simple example reflects a fundamental point—mutual ignorance is just as effective as mutual understanding at preventing adverse selection.

In many markets beyond new cars, functioning depends on market participants *not* having all pertinent information, and there are benefits from this type of market structure. Mutual ignorance can facilitate the provision of liquidity and can be critical to sustaining pooling equilibria.<sup>150</sup> Moreover, because information gathering and analysis is costly and

<sup>147</sup> *Id.*

<sup>148</sup> *Id.*

<sup>149</sup> While not the focus of Akerlof’s analysis, there are also a variety of contractual tools, like warranties, that a dealer who sells a high volume of new cars could more readily deploy in order to signal quality and to divorce the transfer of the car from the anticipated costs that will arise if it is a lemon.

<sup>150</sup> *E.g.*, Michael J. Fishman & Jonathan A. Parker, *Valuation, Adverse Selection, and Market Collapses*, 18 REV. FIN. STUD. 1 (2015) (finding that “[b]ecause the private benefits to valuation exceed its social benefits, the equilibria with lower levels of valuation are more efficient”); Holmstrom, *supra* note 10, at 12, 15–16 (noting that “[i]ntentional opacity is a rather ubiquitous phenomenon” and describing a wide array of markets that use structures that rely on limited access to information); André Stenzel & Wolf Wagner, *Opacity and Liquidity* (CEPR discussion paper No. DP10665, 2015), [http://papers.ssrn.com/sol3/papers.cfm?abstract\\_id=2621569](http://papers.ssrn.com/sol3/papers.cfm?abstract_id=2621569) (formally modeling why “it can be (privately and socially) optimal to issue opaque assets such as to deter information acquisition” and that “[i]t

sometimes socially wasteful, there can be welfare gains from market structures that reduce the need for such activities.<sup>151</sup> These benefits and the cost of producing information lead to the second building block—the level of information production that will be optimal in a given market cannot be determined in the abstract. There may well be market structures that are viable but socially suboptimal for information-related reasons, as information-thin market structures are more fragile and encouraging information production may produce positive externalities. Nonetheless, virtually all markets can tolerate some information gaps and some may require such gaps.<sup>152</sup>

The third building block is that the effect of new information on market functioning and the processes through which markets incorporate new information depend on market structure. This supposition is illustrated by returning to the differences between equity and money markets. These markets typically achieve the relative parity in information required for trade in quite different ways. Equity markets “level up” the informational playing field through publicly observable prices that contain meaningful information about the value of the underlying assets. This works because the same processes that reward sophisticated investors for engaging in costly information gathering and analysis simultaneously push prices to relatively more efficient levels. At the same time, public and private institutions that enhance the efficiency of these markets simultaneously promote market functioning, as the more accurate an otherwise uninformed investor perceives prices to be, the more rational it will be for him to acquire an equity claim without engaging in costly diligence.

Money markets, by contrast, often “level down” through claim structures that make it costly and unrewarding for claimants to acquire superior information about the underlying assets. Such arrangements are both necessitated and facilitated by the payoff structure of money claims; as is the case with all debt instruments, money claimants receive no additional return if the value of the assets backing their claim exceed the par value of that claim.<sup>153</sup> This means, for example, that the holder of a money claim with a par value of \$10,000 who has access to a reliable proxy indicating that the value of the assets backing that claim is between \$20,000 and \$30,000 has no reason to gather the information required to more precisely value those assets. The lack of any upside removes any incentive to engage in due diligence so long as a claimant has reason to believe the

---

can even be desirable to artificially increase an asset's opacity beyond its natural level”); Carapella & Mills, *supra* note 92, at 36–37 (arguing “information insensitivity is desirable because it allows trades to occur easily”). The importance of pooling equilibria is also much discussed in the literature on insurance.

<sup>151</sup> *E.g.*, David Andolfatto et al., *Optimal Disclosure Policy and Undue Diligence*, 149 J. ECON. THEORY 128–52 (2014); Daniel G. Goldstein, *Undue Diligence*, 20 BUS. STRATEGY REV. 16, 16 (2009) (“[C]ollecting and analyzing all available data may turn out to be *undue* diligence.”) (italics in original); Jack Hirshleifer, *The Private and Social Value of Information and the Reward to Inventive Activity*, 61 AMER. ECON. REV. 561, 573 (1971) (showing that “[p]rivate information that remains private ... [has] no social value—in the sense of being purely redistributive, not leading to any productive arrangements” and “[t]here is an incentive for individuals to expend resources in a socially wasteful way in generation of such information”).

<sup>152</sup> Even equity markets, where information gaps tend to be quite small and short-lived, depend on those modest gaps to incentivize the information gathering and analysis required to help them remain informationally efficient. This insight from Gilson and Kraakman enabled them to explain why why Sanford Grossman’s efficiency paradox is not a paradox in practice. Gilson & Kraakman, *MOME*, *supra* note 28, at 623.

<sup>153</sup> *See* Holmstrom, *supra* note 10, at Figure 1 and accompanying text.

value of the underlying assets comfortably exceeds the value of her claim. These are among the reasons that money claimants rely on proxies suggesting that a claim is exceptionally low risk coupled with a right to exit, quickly and at face value, as a substitute for high-quality information.

This lays the foundation for another important difference between money and equity markets—how they respond to new information. Equity prices typically respond to new information in an incremental fashion, going up or down proportionately as new information enters.<sup>154</sup> Money markets operate quite differently. In information-thin money markets, new information will either have no observable impact or trigger dysfunction. Put differently, information that accords with the assumptions that underlie a money claimant’s willingness to rely on a particular proxy as strongly indicative that her claim is exceptionally low risk should have little impact on pricing or market functioning. By contrast, information that suggests that her claim is higher risk than she previously believed or that casts doubt on the accuracy of a proxy on which she had been relying might well cause her to walk away. This leads to significant nonlinearities in how money markets respond to new information, in stark contrast to equity markets. This also leads to the fourth and final building block—the effect of information and information gaps on market functioning can be state contingent.

### C. Information gaps and systemic stability

Building on these four understandings, this Article argues that information gaps in any regime that relies on money claims for a meaningful amount of capital accentuate the fragility that arises from that reliance and are likely to exacerbate the degree of market dysfunction when confidence gives way to panic. This subpart explains why the range of signals that might trigger a change of state are expanded and the process of restoring confidence should panic take hold is hampered when information gaps are large. Part IV establishes that the conjectures made here are consistent with quantitative and qualitative information about how events unfolded during the Crisis. The different issues discussed here all arise from the common challenge posed by information gaps—it is costly to produce information and, when those costs are high because the gaps are large, this can result in significant frictions limiting the capacity of market participants and regulators to respond in a timely and appropriate way to new developments.

The analysis that follows focuses first on whether money claimants are likely to run and then on the ways that other market participants and regulators will respond if and when money claimants withdraw, but this breakdown is used merely for purposes of exposition. Each set of developments is closely intertwined with and to some extent contingent upon the others. If money claimants expect government backstops, for example, this could halt a run before it begins. Similarly, if loss-absorbing capital could instantly come in to fill the shortfalls created when money claimants exit, this would obviate the need for fire sales and the market dysfunction that arises when money claimants run. Thus, this Article’s claims about the probability of a panic and the scope and duration of the market dysfunction that arises as a result are really just variations on a

---

<sup>154</sup> Bubbles represent an important exception to this general rule. Yet, bubbles are the exception rather than the norm and, as reflected recently by the popping of the dot.com bubble, even large stock market bubbles can burst without necessarily inflicting the type of adverse effects on the real economy that follow dysfunction in money markets. *See generally*, RICKS, *THE MONEY PROBLEM*, *supra* note 4.

common claim—the frictions imposed on the capacity of an intermediation regime to acclimate to certain types of information can significantly exacerbate the market dysfunction that results from such a trigger.

### 1. Tendency to run

Recognizing that money claimants almost always have radically incomplete information about the assets underlying their claims is critical to understanding when they are likely to exercise their right to exit, and thus when we are likely to see destabilizing runs. Switching and other costs create a small friction on money claimants' disposition to make withdrawals in situations where they continue to prefer holding some type of money claim to cash. Nonetheless, money claimants are holding money claims because they are seeking an instrument that is so low risk they do not need to engage in any meaningful due diligence. Thus, even a modest amount of credit risk or an inability to be confident that the credit risk is low could trigger withdrawals.

Economists often explain runs using one or both of two paradigms.<sup>155</sup> One view, espoused most famously by Diamond and Dybvig, posits that runs arise from coordination problems among money claimants.<sup>156</sup> Because this view depicts runs as self-fulfilling prophecies which can occur independent of any substantive change in the underlying assets or money claimants' beliefs about the same, it is often labeled the “sunspot” theory of runs.<sup>157</sup> A number of subsequent studies provide rich accounts of the mechanisms that might underlie such runs, but they tend to share the common challenge of having little predictive power and no inherent stopping point.<sup>158</sup> An alternative view posits that banking panics are extensions of the business cycle.<sup>159</sup> In this view, panics are “caused by depositor revisions in the perceived risk of bank debt,” typically triggered by a signal of a pending economic downturn.<sup>160</sup> Many contributions that depict runs as arising from fundamentals suggest that information asymmetries between banks and money claimants are critical to explaining runs on solvent institutions.<sup>161</sup> While some models lie between these two paradigms,<sup>162</sup> the sunspot and business cycle theories remain the two

ECON. 97, 99–102 (2009) (explaining that the literature generally falls into two camps—one of which “maintains that panics are undesirable events caused by random deposit withdrawals unrelated to changes in the real economy” and a “second set of theories of banking crises [suggesting] that they are a natural outgrowth of the business cycle” and identifying the main contributions to both).

<sup>159</sup> E.g., Charles W. Calomiris & Gary Gorton, *The Origins of Banking Panics: Models, Facts, and Bank Regulation*, in FINANCIAL MARKETS AND FINANCIAL CRISES 107 (R. Glenn Hubbard, ed., 1991) (identifying this view as running through a number of models and showing that it is consistent with historical evidence from the period between the adoption of the National Bank Act and the founding of the Federal Reserve); Franklin Allen & Douglas Gale, *Optimal Financial Crises*, 53 J. FIN. 1245–1284 (1998).

<sup>160</sup> Calomiris & Gorton, *supra* note 159, at 111.

<sup>161</sup> E.g., Allen, Babus & Carletti, *supra* note 155, at 100 (describing the theories that rely on information asymmetries).

<sup>162</sup> Allen et al., *supra* note 157, at 2–3 (providing an overview of the two main theories and the recent literature suggesting an intermediate interpretation); Gorton & Winton, *supra* note 155, at 507–08 (summarizing the alternative theories). In part because the information-based set of theories has tended to

most influential paradigms for bank runs. This is reflected in the fact that empirical studies of runs by money claimants continue to attribute withdrawals that can be explained by changes in credit risk or other fundamentals to the latter model while attributing run-like behavior that cannot be so justified as evidence of sunspots.<sup>163</sup>

Recognizing information gaps suggests another mechanism that could cause runs to exceed the scope justified by the increased credit risk while nonetheless being driven by information, or rather lack thereof. As a starting point, subject to modest frictions, it is rational for a money claimant to withdraw when new evidence (1) reveals that a claim has appreciable credit risk, and thus is information sensitive; or (2) renders it unclear whether a claim is sufficiently low risk to justify information insensitive treatment. Because information gaps make it more difficult for a money claimant to assess whether a signal bears on the value of the specific assets underlying its claim, information gaps increase the types of information that fall into category two. As a result, the larger the information gaps that exist, the greater the range of signals that could trigger a run. To make this more concrete, the type of signals that might trigger a run need not be limited to ones that indicate banks generally will underperform, such as a looming recession.<sup>164</sup> Rather, any signal that suggests some subset of the assets backing some money claims are riskier than previously believed and which belies the reliability of a proxy on which money claimants had relied to conclude their claims were so low risk as to merit information insensitive treatment could trigger widespread withdrawals.

In contrast to many of the other information-based theories of bank runs, the mechanism proposed here does not require information asymmetries and can occur even when money claimants do not anticipate adverse selection.<sup>165</sup> Money claimants run because they are unable—without undertaking due diligence in excess of the amount that is cost justified—to assure themselves that a claim they are holding is sufficiently low risk to justify ongoing treatment as if it is information insensitive. This means that the presumption of mutual ignorance could hold even during a period of widespread withdrawals.<sup>166</sup> While not ruling out the possibility of sunspots, this frame provides a way to understand runs not readily explained by credit risk as nonetheless being driven by information, or rather, lack thereof.

---

be more elastic in what it can reach, one could characterize the intermediate models as instead extensions of the information-based set of theories.

<sup>163</sup> See *infra* Part IV.A.

<sup>164</sup> *Id.*; see also Gorton & Winton, *supra* note 155, at 505 (identifying the fact that “a recession is looming” as the paradigmatic signal triggering panic in the information-based theories of bank runs).

<sup>165</sup> In many ways, this view updates the approach taken by Charles Calomiris and Gary Gorton in identifying a link among the information-based theories by building on their insight that institutions matter and can affect how vulnerable a particular regime will be to a run while extending their intuitions to an environment in which shadow banks rather than banks issue money claims, and the information challenge is one of common ignorance rather than information asymmetries.

<sup>166</sup> This is one of the core ways this Article differs from related work by Samuel Hanson and Adi Sunderam arguing that insufficient information production may have contributed to the Crisis. In their model, there are some fully informed agents; just too few of them. This distinction creates a state where concern about adverse selection drives would-be buyers from the market. The analysis here, by contrast, suggests that at least some of the market dysfunction was due not to concerns about adverse selection by the party on the other side of a trade but by simple lack of information revealed to be relevant. Samuel G. Hanson & Adi Sunderam, *Are there too many safe securities? Securitization and the incentives for information production*, 108 J. OF FIN. ECON. 565 (2013).

## 2. Shock absorbers

The fragility arising from information gaps is exacerbated by the ways that information gaps impede the market and regulatory processes that can prevent an adverse signal from triggering a widespread panic and that can help restore stability once panic takes hold. One way for the government to prevent and contain runs is to guarantee money claims.<sup>167</sup> Such a policy can be instituted *ex ante*, as in the case of FDIC insurance, or *ex post*, as occurred when the Treasury Department backstopped money market mutual funds to stem withdrawals after the failure of Lehman Brothers caused one fund to break the buck.<sup>168</sup> By rendering both risks and unknown unknowns irrelevant to the expected return on a money claim, insurance and implicit guarantees significantly reduce money claimants' tendency to run.<sup>169</sup> So long as the insurer is creditworthy and committed, no other information matters and the claim becomes effectively information insensitive.

While exceptionally potent, insurance regimes also entail real costs. One challenge is the moral hazard that inevitably results.<sup>170</sup> Another is that when the government provides insurance, it exposes itself to credit risk. The banking system has never fully resolved these challenges, but the extensive supervisory and regulatory regime governing banks goes a long way toward reducing them.<sup>171</sup> Guarantees can play similarly helpful roles promoting stability outside the regulated banking sector, but the associated moral hazard and credit risk increase dramatically in the absence of a comparable *ex ante* regulatory scheme.

A second way that regulators can promote market functioning when market participants become concerned about information that they lack is to help fill the gaps. As Federal Reserve Governor Tarullo has explained, once a crisis takes hold, “the only way that market actors are going to start regaining any confidence is if they think they understand what is going on.”<sup>172</sup> Injecting credible information into the system can help quell a panic by convincing some money claimants that their claims are still sufficiently

low risk to merit treatment as money.<sup>173</sup> Information injections can also play a critical role in reducing the frictions inhibiting the entry of informed, loss-bearing capital by reducing the information generation such capital holders must undertake to assess whether a claim is appropriately priced. Again, this is a technique long employed by bank examiners, alongside their tendencies toward confidentiality. It was even used by private actors seeking to restore stability before banks were as thoroughly regulated.<sup>174</sup> Nonetheless, it is not a viable policy tool when the government lacks credible information.

A third tool frequently employed to mitigate financial crises is for a central bank to provide fresh liquidity to the banks or other entities facing liquidity constraints, reducing the need for the value-destroying fire sales which can otherwise be a powerful mechanism of contagion. The standard way central banks provide fresh liquidity is through collateralized loans, which enable a bank or other entity to post less liquid collateral in exchange for cash equivalents or other liquid assets.<sup>175</sup> Without high-quality information about the actual value of the assets pledged as collateral, however, or the soundness of the firms pledging that collateral, the line between liquidity support and credit support quickly blurs, and interventions designed to help restore stability can instead exacerbate the fragility, delay necessary transfers, and engender excessive moral hazard.<sup>176</sup>

This leads to a fourth strategy for helping to restore stability, which is to recapitalize the entities issuing the money claims. Concerns about the value of underlying assets often indicate a need for more capital that is able to bear risk. Again, this is a strategy long used to restore stability when banking crises hit. Yet, information gaps again make this strategy more difficult to deploy: the less information policymakers have about asset values, associated risks, and the distribution of risks across a financial system, the less able they are to tailor capital injections to the scale and scope of the problems they are facing. This can lead to delays, increasing the size and scope of a financial crisis. It can also result in the provision of excess capital, increasing moral hazard and the credit risk to which the government is exposed.

<sup>173</sup> Calomiris & Gorton, *supra* note 159, at 160–62.

<sup>174</sup> For example, in engineering the end of the panic of 1907, J.P. <sup>176</sup> *Id.*

<sup>176</sup> *E.g.*, Judge, *The First Year*, *supra* note 175 and sources cited therein.

Yet to understand why information gaps pose such a challenge during periods of systemic distress, it is important to bear in mind that market participants also lack the pertinent information. This is key because the optimal role for regulators is often to work with, rather than supplant, private actors. When new capital is needed, capital should ideally come from private sources and the influx of loss-absorbing capital should result in the production of some of the missing information. Market participants will not enter, however, unless the expected returns exceed the sum of the expected cost of the assets and the cost of undertaking the information gathering and analysis required to make wise acquisition decisions. Sizeable knowable but unknown unknowns thus create large hurdles, reducing the likelihood that private capital will enter in a timely fashion or the holders will be willing to sell at the prices such buyers might be willing to offer.<sup>177</sup>

Critically, just as with the explanation provided here for bank runs, understanding these frictions highlights the importance of recognizing information gaps and distinguishing them from the more commonly recognized frictions typically associated with information asymmetries and concerns about adverse selection. The analysis here reveals new dynamics that operate alongside known frictions, ones that are critical for developing a robust understanding of the ways that complexity and incomplete information affect fragility.

#### IV. The Role of Information Gaps in the Crisis

Having established theoretically why information gaps are likely to flourish in the shadow banking system and contribute to its fragility, the question becomes whether the evidence supports this Article's conjectures. This Part uses the Crisis to explore these issues.<sup>178</sup>

##### A. Escalation

It is widely, though not universally, recognized that the Crisis started in August 2007.<sup>179</sup> The information that eventually triggered the market dysfunction that erupted that August had been building for some time. The housing market started to weaken in late 2006, adversely affecting the demand for mortgage-backed securities (MBS), particularly those backed by subprime loans, which were revealed to be more risky than previously believed. By the end of July 2007, the lead credit rating agencies had engaged in record downgrades, downgrading well over 1,000 subprime MBS.<sup>180</sup> The ABX index for lower rated subprime MBS, an important mechanism aggregating views on the value of subprime MBS, was also declining throughout 2007.<sup>181</sup> Nonetheless, it was not until

August 9<sup>th</sup>, when BNP Paribas announced it was temporarily suspending redemptions in three funds because of a lack of liquidity in the subprime MBS market, that the bad news that had been building all summer led to widespread market dysfunction.<sup>182</sup> The lack of symmetry between the way that the information gradually built up over time and the dramatic, nonlinear shift in the way that information affected market functioning is consistent with the description of how money claimants—as opposed to equity claimants—respond to new information.<sup>183</sup>

Empirical evidence supports that there was a “run” on ABCP starting in August 2007. Daniel Covitz and co-authors use data on all ABCP issued in the United States in 2007 to show that the market was remarkably stable for the first half of the year despite the accumulating bad news and then disintegrated quickly.<sup>184</sup> Covitz and his co-authors found that prior to August, “[t]he percent of ABCP programs in a run... was quite low.... Starting in August, the percent of ABCP programs experiencing a run each week climbed sharply.”<sup>185</sup> By September, more than “30 percent of all ABCP programs” had experienced a run and “[b]y the end of 2007, more than 40 percent of programs were in a run.”<sup>186</sup> Among other ramifications, this resulted in a dramatic decline in the amount of ABCP outstanding.<sup>187</sup>

Significantly, while the proportion of ABCP programs that experienced a run is high and represents a significant dislocation in what had been a large and seemingly stable market, the figure is well shy of 100%. “[I]nvestors were more likely to run from programs with substantial exposure to mortgage-related assets,” programs that had terms giving the sponsors the right to extend the term of ABCP, and “programs with greater credit and liquidity risk,” consistent with the notion that the money claimants were minimally informed, not uninformed.<sup>188</sup> Additionally, while Covitz and his co-authors claim that in August and September, ABCP holders also engaged “indiscriminate runs,” they base that conclusion on the fact that some of the runs cannot be explained by fundamentals.<sup>189</sup> Yet if the runs were truly indiscriminate, it is hard to explain why not all ABCP programs experienced runs. The analysis here suggests a distinct rationale that helps reconcile their finding that not all of the runs can be explained by fundamentals with the finding that ABCP holders did not run from all funds—ABCP holders may have run when the fundamentals so justified or when they lacked information about the program’s exposure to problematic assets. That the runs occurred following a signal that suggested problems with respect to only a small subset of the assets backing ABCP is also consistent with this Article’s claims regarding the ways information gaps increase fragility by expanding the range of signals that can trigger a run.

Holders of other money claims that had supported the shadow banking system engaged in similar run-like behavior. Gary Gorton and Andrew Metrick, for example, document a run on repo—another money claim issued in the shadow banking system—that also started in August 2007 and became more pronounced following the failure of Lehman Brothers in September 2008.<sup>190</sup> Their focus is on “haircuts,” the degree of overcollateralization that holders demanded to treat a claim like money. As Gorton and Metrick explain, rising haircuts function like withdrawals because they reduce the amount of funding that a firm can obtain using particular collateral. Again, the evidence shows significant nonlinearities in how money claimants responded to new information depending on the type of collateral that backed a money claim. The degree of overcollateralization money claimants demanded increased in accord with rising “uncertainty about collateral values,”<sup>191</sup> and it became virtually impossible for parties seeking to issue money claims to use the most opaque and difficult-to-value assets as collateral.<sup>192</sup> Given that more complex assets are likely to be only incompletely understood by either party to a repo transaction, that haircuts increased most dramatically for such assets is yet another finding that is more consistent with the notion that information gaps drove some subset of the run behavior than theories that depend on information asymmetries to explain runs.

The escalation of the Crisis entailed similar dynamics. For example, among the factors contributing to the magnitude of the adverse ripple effects of the Lehman Brothers failure was the impact of that bankruptcy on money market mutual funds. The day after Lehman’s bankruptcy, one money market mutual fund holding CP issued by Lehman Brothers “broke the buck,” causing it to redeem shares, at the lowest point, at \$0.97 per share, before going through an orderly resolution that provided holders \$0.99 for each share that under ideal circumstances would be worth \$1.00.<sup>193</sup> Despite the relative modesty of these losses, many money market mutual fund holders reacted by quickly exercising their right to exit. Again, subsequent empirical analysis confirms “run-like behavior,” and that this behavior varied across fund types.<sup>194</sup> Institutional investors were far more likely to exit than retail investors; and, although institutional investors withdrew massive amounts of capital from funds holding non-government assets, they simultaneously acquired shares in money market mutual funds holding “U.S. Government-backed securities.”<sup>195</sup>

In all of these instances, money claimants had been providing capital consistently despite having limited information about the assets underlying their claims and the risks to which those assets were exposed. The withdrawals thus were not triggered by the fact that holders lacked material information; the information gaps predated the runs. Moreover, in most of these instances, there was a notable asymmetry between the incremental buildup of bad news and the way money claimants reacted to that

information. The claims were structured to be information insensitive, and so money claimants did not respond in any meaningful way to the first (and second and third...) signs of bad news. Nonetheless, when bad news was coupled with information suggesting that the proxies money claimants had relied on were less accurate than previously believed, money claimants exited quickly. And, when they did, they did not withdraw from everything, nor did they withdraw only when doing so was justified by increased credit risk. Rather, the withdrawals followed an intermediate course precisely as the analysis here predicts.

The data examined here represent only a subset of the work that has been done on the Crisis and other periods of systemic distress, but they also represent some of the more important empirical work on the fragility of the shadow banking system. It is thus notable, even if far from conclusive, that this evidence comports with this Article's claims.

### B. Restoring stability

The Crisis also illustrates how information gaps impede the public and private processes that can restore stability when money claimants run. As an initial matter, all of the "runs" on the shadow banking system occurred in part because there was no insurance scheme or established liquidity facility in place deterring money claimants from running. Similarly, policymakers were not in a position to assure money claimants regarding the value of the assets underlying their claims or to help money claimants discern which claims were most likely to be exposed to problematic assets because the government did not have any superior information about such matters. Additionally, while the government eventually did recapitalize important components of the financial system, it did not intervene to provide capital support until well over a year into the Crisis, and the scope of the Crisis grew significantly during the interim. The lack of information leading policymakers possessed appears to have contributed to that delay.<sup>196</sup> Moreover, the Crisis was escalating throughout 2007 and much of 2008 in part because informed capital was not coming in to counteract the vacuum created as money claimants fled from an ever-expanding array of markets. Concurrent assessments of the market dysfunction suggest information gaps were a significant contributing factor.<sup>197</sup>

Policymakers ultimately used all of the tools long used to address banking crises—guarantees, liquidity support, information injections and fresh capital. They did so in significant part because they recognized that failure to do so would have resulted in even greater market dysfunction and more adverse spillover effects on the real economy. The Fed's many temporary liquidity facilities, its support of Bear Stearns and AIG, the Treasury's provision of explicit insurance policies for money market mutual funds and the credit and other support that the Treasury provided to banks through the Troubled Asset Relief Program were all mechanisms of assuring short-term and other creditors. Yet—in stark contrast to the banking regime—there was no *ex ante* system of controlling the activities in which these entities engaged and the assets they could hold, nor was there a supervisory regime providing regulators high-quality information about the risks of the underlying assets.

<sup>196</sup> See Judge, *The First Year*, *supra* note 175.

<sup>197</sup> *Id.*

As reflected in Dodd-Frank Act and other post-Crisis reforms, the expansion of the government safety net to nonbank firms is widely perceived as having created significant moral hazard, requiring the adoption of extensive and quite costly regulatory reforms.<sup>198</sup> Less commented on but no less important is how the dearth of information that the government possessed when it extended liquidity and credit guarantees increased the effective credit risk that the government assumed. The government, for example, ultimately profited from the interests in AIG it obtained in connection with helping the firm avert bankruptcy, but that by no means alters the accuracy of Treasury Secretary Timothy Geithner's statement that he "thought we were taking enormous, unprecedented risks and that there was substantial risk that we would lose billions of dollars, if not tens of billions of dollars" when it first took that action.<sup>199</sup>

Policymakers also directly targeted the information gaps that were inhibiting market functioning. The most clear-cut example of policymakers using information injections to promote market functioning was the public disclosure of the results of stress tests conducted on the largest banking holding companies.<sup>200</sup> As then-Fed Chairman Bernanke later explained, the Fed recognized that "[t]he loss of confidence we have seen in some banking institutions has arisen not only because market participants expect the future loss rates on many banking assets to be high, but because they also perceive the range of uncertainty surrounding estimated loss rates as being unusually wide" and the stress tests were "designed to reduce this uncertainty."<sup>201</sup> In opting to publicly disclose the results of the tests, Fed policymakers reasoned that, given that uncertainty remained pervasive and was itself adversely affecting market functioning, "[e]ven a mixed bag of information about the actual condition of banks" would enhance market functioning.<sup>202</sup> The market's response to the stress tests supported the conjecture.<sup>203</sup> As Bernanke later opined, the stress tests were "critical turning points in the financial crisis," because they "provided anxious investors with something they craved: credible information about

The willingness of Fed officials to undertake tests that were sufficiently robust to be credible and to commit to disclosing the results also rested upon the fact that Congress had authorized Treasury to provide significant capital support to the banking system, so it was clear that the government could and would use taxpayer funds to recapitalize any banking organizations revealed to be deficient. Morgan et al., *supra* note 203, at 1482 (explaining how in 2009 stress test, "[b]anks with [capital] gaps were required to file capital plans describing how they intended to fill the gap (whether privately, via conversions, or via [Capital Assistance Plan]) by November 2009").

prospective losses at banks.”<sup>204</sup> The stress tests are a good example of effective crisis management. Nonetheless, that they occurred only after the Crisis had been underway for a prolonged period of time and after the government had significantly expanded its safety net illustrates the mismatch between the regulatory structures in place and regulators’ capacity to address the challenges they faced. While far from exhaustive, this subsection and related work highlight the ways that information gaps arising from the many things that *no one* knew about the shadow banking system affected the capacity of regulators to deter money claimants from running, the drawbacks of the government interventions eventually implemented and the degree to which they could enlist the help of other market participants in their efforts to restore stability.

### C. Qualitative support and the importance of terminology

How policymakers talked about the challenges they were facing during the Crisis provides further support for the importance of identifying information gaps as such. Even during the early phases of the Crisis, Federal Reserve Governor Frederic Mishkin and others recognized that “[t]he issue is that there’s an information problem in the markets.”<sup>205</sup> They also recognized that the rise of the shadow banking system limited the amount of information they had about those challenges. As Governor Donald Kohn observed, “In the old days, we used to know where the risks were; unfortunately, we knew that they were all on the bank balance sheets. With the originate-to-distribute model and securitizations[—core components of the shadow banking system—]... the risks are much more dispersed.”<sup>206</sup> He further noted that this “leads to potential pockets of uncertainty, and that is exactly what has come up.”<sup>207</sup>

Policymakers even were attuned to many of the specific mechanisms through which the information problems were causing the market dysfunction to spread. As Kohn explained: “A critical channel of contagion ... was the involvement of banks as providers of credit and liquidity backstops in the ABCP market” which caused “uncertainties about real estate markets, the performance of nonprime mortgages, and structured-credit products [to come] to rest as greater uncertainty about bank exposures.”<sup>208</sup> Other Fed officials made similar observations.<sup>209</sup>

Because current theories fail to provide a term that conveys the challenge as one entailing information that was pertinent and knowable but not known to anyone, however, Fed policymakers were forced to describe the challenge in established, but less accurate, terms. For example, Fed officials often characterized the problem as a challenge of “uncertainty.” This is not necessarily wrong, as the challenge was a problem of unknown unknowns. Yet, by failing to distinguish between Knightian uncertainty, which is exogenously determined and outside the power of anyone to control, and information

gaps, this framing may have limited policymakers' appreciation of the types of tools that could be brought to bear.

Reflecting the fact that some policymakers recognized that the missing information was knowable and thus not traditional Knightian uncertainty, they at times instead invoked the notion of asymmetries to describe the challenges they were facing. For example, in assessing the market dysfunction that surrounded MBS, Bernanke explained:

[W]e have seen the breakdown of a particular structure of lending that was based on the credit ratings. The credit ratings have proven to be false. Therefore, there is an informational deficit—an asymmetric information problem, would be my interpretation—which has, in turn, triggered a massive change in preferences.<sup>210</sup>

Bernanke is certainly correct that there was an “informational deficit.” Nonetheless, in choosing to frame the problem as an asymmetry, he is using a characterization that elides the fact that no one had the relevant information.

Language alone cannot solve difficult problems and there is no easy solution to the dynamics highlighted here. Nonetheless, that Fed officials lacked a term that accurately captured the information dynamics they saw as contributing to the market dysfunction during the Crisis certainly did not enhance, and may well have inhibited, their efforts to respond to those challenges. Expanding the conceptual framework to recognize information gaps and recognizing how they contribute to fragility are thus critical steps to forging a more productive path toward addressing these issues.

## V. Looking ahead

Identifying information gaps as among the factors contributing to the fragility of the shadow banking system raises a number of policy issues about the optimal level of information production, who should produce that information, when and how it should be disclosed, and the extent to which information-related challenges justify structural limits on shadow banking and other activities.

There are no easy answers to these questions, just as there is no easy way to create a system that fulfills the valuable economic functions currently played by the shadow banking system without simultaneously creating systemic risk, but they are critical questions to address. As reflected in the remarkable stability of the banking sector for most of the last century and the variation in the stability of different banking sectors across different countries, design features can meaningfully affect fragility.<sup>211</sup>

This Part distills some of the key lessons that can be derived from the analysis here. It begins by highlighting the need for a fundamentally new financial regulatory paradigm to govern shadow banking. It then considers the implications of this Article's insights with respect to shadow banking reforms underway and further reforms that may be warranted.

### A. A new regulatory paradigm

One lesson is that the shadow banking system is a hybrid system, one that shares much in common with the capital markets and banks as traditionally constituted, but which cannot be fully understood within either paradigm. This raises important questions regarding regulatory competencies and the appropriate regulatory framework. It casts doubt, for example, on whether the SEC, as a securities regulator, is the best agency to oversee money market mutual funds, which pose risks of the type normally addressed through prudential regulation. It also provides fresh support for the importance of institutions like the Financial Stability Oversight Council (FSOC), which brings securities regulators and prudential regulators and asks them to work together to identify and address sources of systemic risk.

The analysis also suggests there might be real gains from deeper interdisciplinary engagement among academics and other experts. The different assumptions that various experts implicitly bring to the table are reflected in their distinct diagnoses of the Crisis and competing proposals for further reform. While sometimes glossed over by various framing devices, the differences often run quite deep.

For example, in recent work, legal academics Ronald Gilson and Reinier Kraakman expand the insights on the mechanisms of market efficiency to markets populated by instruments beyond equity claims and domains where primary markets dominate secondary ones. This leads them to conclusions that overlap with this Article's claims—lack of information and the costs of producing that information played important roles contributing to the scope of the Crisis.<sup>212</sup> While engaging in an institutional analysis that recognizes that the holders of many of the instruments issued in the shadow banking system may be disinclined to undertake any due diligence, they nonetheless identify more robust mandatory disclosure requirements as an important component of the optimal policy response.<sup>213</sup> Responding to that suggestion, economist Bengt Holmstrom is dismissive. In his view, “the logic behind transparency in stock markets does not apply to money markets.”<sup>214</sup> In his view, they have the “wrong diagnosis of [the] problem” and that “to minimize the chance of new, perhaps worse mistakes, we need to analyze remedies based on the purpose of liquidity provision.”<sup>215</sup>

The analysis here suggests that the optimal route forward may lie between these visions—on a path that incorporates Gilson and Kraakman's insights regarding the importance of information costs while also taking into account Holmstrom's insights regarding the distinct characteristics of money markets. Holmstrom's critique likely underestimates the important role that more robust disclosure policies could play in limiting information gaps and the fragility that results when such gaps arise in financial systems dependent on capital from money claims. Yet Holmstrom's critique is not without merit. A core rationale for mandatory disclosure in securities regulations is that the issuer is the lowest cost producer of such information. In a world where the issuer of an instrument is a specially created vehicle holding complex assets and the holders of the money claims that the vehicle will issue are relying on the complexity of the underlying

<sup>215</sup> *Id.*

assets to ensure that the issuer and its sponsor have no private information about the value of those assets, such an assumption does not hold.

Gilson and Kraakman have a partial response to this, as the specific disclosure regime they propose focuses on tracking the underlying credit instruments that provide financing to the real economy so that those instruments can be more easily traced through the layers of fragmentations nodes in which those instruments are bundled with other instruments and new instruments are created.<sup>216</sup> Yet, in his analysis, the process of imposing such requirements could upset the very infrastructure on which such markets currently rely. Viewed through the lens of the stylized example of Akerlof's car market, the spirit of Holmstrom's critique is that subsidizing the development of technology that would allow buyers in the used car market to more easily identify lemons risks throwing the baby out with the bathwater by undermining the viability of the primary market.

The debate, of course, does not end there—just as a seller of new cars might use warranties or other mechanisms to overcome the introduction of new asymmetries, money markets may evolve in ways that allow money claimants to remain minimally informed despite regulatory changes that would lower the cost of producing pertinent information. Moreover, as Gilson and Kraakman highlight, their proposal is motivated not only by concerns about the markets in which these various financial claims trade, but the origination processes that produce the underlying assets. They view greater ongoing scrutiny of origination processes as an important mechanism for ensuring that those practices do not become excessively lax as a result of the information gaps that would otherwise exist.<sup>217</sup> The aim of this hypothetical back and forth is not to resolve this debate but to highlight the important and quite different insights that both sides bring to the table.

Taking a step back, the analysis here highlights the value and limitations of each approach to assessing the challenges posed by shadow banking. Consistent with Holmstrom, this examination emphasizes the importance of recognizing that the institutional competencies of equity and money holders arise less from the nature of the holder and more from the nature of the claim that they hold. Many large, sophisticated investors hold both equity and money claims but they hold the claims for different reasons: the equity claims are investments on which they hope to profit; the money claims are ways to store liquidity. No amount of information or other regulatory change is going to transform their approach to money claims to resemble their approach to equity claims. For this reason, reform proposals that expect market participants will engage in meaningful information gathering or that otherwise seek to force money claimants to act like holders of securities that are held for investment will fall short if not coupled with other reforms.

At the same time, the analysis here also suggests that fully embracing the alternative view sometimes advocated by those who understand banking—that we should accept instability as part of how the system works, applaud the massive support provided by the government during the Crisis, and extend the scope of the formal government safety net—would lead to reforms that are suboptimal for different reasons. The fact that

---

<sup>216</sup> Gilson & Kraakman, *Information Costs*, supra note 29, at 354–55.

<sup>217</sup> *Id.*

shadow banking occurs in the capital markets raises important questions about the mechanisms for imposing discipline on the processes creating the underlying assets and the subsequent monitoring required to maintain the value of those assets, in addition to posing the fragility challenges highlighted here. Many mechanisms that promote stability come at the expense of robust discipline and the optimal balance is unlikely to be achieved without a deep understanding of how discipline can and has been imposed in various settings. In highlighting the differences between money claims and equity claims and the current regulatory paradigms governing each, the analysis here provides critical groundwork for addressing the question of how best to regulate shadow banking.<sup>218</sup>

## B. Implications for reform

This Part considers the implications of this Article's insights on the post-Crisis reforms underway, proposals for further reform, and related policy issues. Because this Article is focused on only a subset of the challenges posed by shadow banking and makes no effort to measure the benefits, the aim here is not to chart the optimal path but to show how this Article's insights inform these ongoing debates.

### 1. Post-crisis reforms

The regulatory reforms already underway make important progress with respect to a number of the challenges highlighted here. For example, the new authority of the FSOC to designate non-bank financial institutions systemically significant and subject them to prudential oversight, coupled with the fact that the largest investment banks have all converted into or been acquired by bank holding companies, significantly expands the scope of the government's supervisory authority. This expansion should meaningfully reduce the magnitude of the information gaps arising from the shadow banking system. Another important development is the creation of the Office of Financial Research (OFR). The OFR, which supports the work of the FSOC, has broad authority to not only gather information but to mandate standardization with respect to the ways financial institutions collect and report certain data. Depending on implementation, the OFR's work could go a long way toward addressing information gaps.<sup>219</sup>

Despite this real progress, core structural challenges remain. Money claims issued by nonbanks remain sizeable in amount and largely outside of the prudential regulatory umbrella,<sup>220</sup> efforts to further reform money market mutual funds remain contested,<sup>221</sup>

---

<sup>218</sup> This point is not novel, but the analysis adds flesh to the claim. *See, e.g.*, Perry Mehrling, et al., *supra* note 10, at 1 (explaining “taking of different approach” from “widespread impulse to frame the question of appropriate oversight and regulation of shadow banking as a matter of how best to extend the existing system of oversight and regulation as it is applied to traditional banking”).

and regulations implementing provisions of the Dodd-Frank Act targeting other aspects of the shadow banking system seem likely to fall short.<sup>222</sup> Just as importantly, the reforms adopted post-Crisis have done relatively little to reduce the complexity of financial instruments and institutions, and that complexity is a significant factor exacerbating information gaps. Many of the reforms also remain focused on institutions, rather than markets, and the process of overseeing the former does not necessarily provide regulators a deep understanding of the latter, a notable shortcoming for reasons here revealed.

Both the progress made and the magnitude of the information gaps that remain are reflected in a recent working paper by the OFR on short-term secured lending and repo, two of the most significant nonbank money markets.<sup>223</sup> In summarizing the findings, the head of the OFR stated: “Data available to regulators and market participants have improved since the crisis but remain insufficient to evaluate the risks or even the level of activity in these markets.”<sup>224</sup> While the OFR has a number of projects underway to address these and other informational shortcomings, its progress remains slow. More generally, the premise underlying the creation of the OFR is one for which there is little precedent. In banking, supervisors play an important role monitoring bank activity, but the information generation in which they engage is coupled with the authority to take actions responsive to risks they identify.<sup>225</sup> The benefits of giving broad information-related powers to an entity that lacks further authority remain unclear.

Taking yet another step back reveals that the shadow banking system continues to grow and we have yet to develop a workable paradigm that addresses the systemic risk that it poses. A shadow banking system subject to little supervision can work very well for an extended period of time. There are a variety of private mechanisms that can enable the issuance of money claims that are largely insensitive to most incremental information. Yet, over time, subtle shifts in asset quality and other risks can build up in the information gaps that spread along with the growth of the shadow banking system. When money claimants become concerned about the information they lack, the short-term nature of

their commitments enable them to exit quickly and without penalty. And when money claimants withdraw en masse, the loss of that capital from a system that had come to rely on it is likely to have far-reaching effects. The growth of the shadow banking system may thus be fueled by decisions that are rational for the persons providing the capital enabling that growth while nonetheless socially suboptimal given the heightened systemic risk. This core challenge remains.

### 3. Structural changes

Accepting that further reforms are needed, the question is what form should those reforms take? Among the reforms for which this Article provides fresh support are structural reforms aimed at simplifying financial instruments and institutions and the interconnections among them. Information gaps, by definition, are subset of pertinent and knowable information. As complexity increases, so too does the amount of potentially pertinent information. Fragmentation nodes, for example, can produce financial instruments that are lower variance than any of the underlying assets. At the same time, these structures transform previously irrelevant issues, like the correlation among the specific assets packaged into that fragmentation node and the contractual terms setting forth the rights of each class of the instruments subsequently issued, into information that is pertinent, and not necessarily known by anyone. The analysis here thus provides fresh support for reforms, both underway and proposed, that seek to reduce the complexity of the financial system and the instruments and institutions that constitute that system.<sup>226</sup>

Complexity can serve socially useful functions and is the byproduct of many legitimate activities, but it also creates frictions in the public and private mechanisms for dampening the ripples that can emanate from bad news and restoring stability when panic sets in. Particularly considering the significant heterogeneity in the degree and types of complexity embedded in different instruments and the probability that any benefits of opacity taper off beyond a certain point, regulations that make it more costly for market participants to create relatively more complex instruments and other reforms targeting complexity are likely to be critical.

Some structural reform proposals go further. Morgan Ricks and Adam Levitin have each proposed reforms that would drastically curtail shadow banking and others, like Andrew Metrick and Gary Gorton, have proposed more modest but still significant structural changes.<sup>227</sup> Most of these proposals suggest that the government should insure a greater swathe of the money claims that get issued. In highlighting the importance of the information cost savings that can arise through mandated simplicity and the ways that guarantees promote stability by rendering otherwise pertinent information irrelevant, the

analysis here provides some new support for these proposals. That said, I remain skeptical that the more extreme reform proposals should be pursued at this juncture. Given the important economic functions the shadow banking system currently plays, the lack of information about the viability and costs of such reforms, and the possibility that having a robust shadow banking system might mitigate the macroeconomic effects of a panic in the banking sector, it is far from clear that such reforms would be beneficial. Right now, we simply do not have the information we need to make an informed assessment of how the benefits stack up against the various costs such reforms could inflict.

#### 4. State dependent information generation

Given the dramatic changes in banking and the growth of the shadow banking system, a complex financial system not fully understood by market participants or regulators is likely to be the new normal. The analysis here highlights how systemic risk can fester in the backwater of market participants' and regulators' ignorance. Information gaps not only increase the probability of a panic, but they also impose meaningful frictions on the processes required to restore stability when concerns arise. The analysis here thus supports claims that financial regulation will inevitably entail both ex ante and ex post interventions, and highlights the need for greater advance consideration of the types of ex post responses that are most likely to contain a growing financial crisis without engendering excessive moral hazard and exposing taxpayers to excessive credit risk.<sup>228</sup>

This Article's insights regarding the fragility arising from information gaps provide particularly strong support for the notion that information generation should be an important component of regulators' ex post strategies and the importance of recognizing the need to start implementing such policies in response to any signal indicating a possible change of state rather than waiting for the eruption of a full-blown financial crisis.<sup>229</sup>

The analysis here assumes that information is costly to generate and that the value of information and the effects of a particular information gap on market functioning are state dependent. Less examined here but developed further in other work is the fact that there is often a meaningful temporal delay between the first signs indicating (and potentially triggering) a change in state and full-fledged market dysfunction.<sup>230</sup> Putting these pieces together suggests that an optimal regulatory approach may entail accepting information gaps, but then rapidly ramping up information production efforts when trouble first hits. Because the early signs of trouble and the market's response to those signs should provide a roadmap to the specific information gaps that are likely to be most problematic, such an approach might allow significantly greater tailoring with respect to the types of information produced.<sup>231</sup> Given the logistic and other challenges inherent in information production and the fact that regulators may well fail to recognize the early indicators of a crisis as such, this type of approach would not displace the need for ongoing information production, but it could alter and lessen that burden.

Other considerations favoring an ex post information production strategy are practical. Almost no one saw the Crisis coming and much of the information that proved critical once the Crisis hit was missing precisely because no one had previously realized that it would be so pertinent. As reflected in the recent work by the OFR and other studies attempting to gauge the size and scope of the shadow banking system, even today massive information gaps remain, and there are likely other issues that may prove critical to the next period of systemic distress that are not even among those regulators are now seeking to better understand. Recognizing the inevitability of information gaps and the ways more aggressive information generation activities during the early stages of a financial crisis might meaningfully contain its subsequent growth provide further support for the value of such strategies..<sup>232</sup>

### C. Beyond shadow banking

The analysis here, while focused on shadow banking, also has important implications for bank oversight. Simultaneous and intertwined with the growth of the shadow banking system has been the rise of a new breed of bank that does not fit the mold that worked so well during much of the 20<sup>th</sup> century. These institutions are large, multinational organizations that engage in a wide array of investment banking and other activities traditionally disallowed for banks and their affiliates. Even apart from their interconnections with the shadow banking system, the scope of these institutions can make it difficult for bank supervisors and even bank management to understand a bank's risk exposures, creating yet new information gaps..<sup>233</sup>

Policymakers' interventions have not always been helpful on this front. Even the Volcker Rule, which proponents depicted as the modern day version of the powerfully simplifying Glass-Steagall wall separating commercial banks and investment banks, makes little progress in this regard. The Volcker Rule may reduce the risks that banking organizations can assume, but the implementing regulations create a complex maze of restrictions for banking organizations and their supervisors.

There are some helpful developments on the bank supervisory front. The ongoing use of stress tests, for example, seems quite helpful, particularly given that regulators seem to be using those tests to push banks to simplify their structures and operations..<sup>234</sup> Nonetheless, bank regulation today looks very different than yesteryear, when limits on bank activities had both the intent and effect of also simplifying banking and facilitating meaningful oversight..<sup>235</sup> This Article's analysis regarding the ways that information gaps

enhance fragility thus also raises concerns about whether the reforms underway for banking are the best ways to enhance the resilience of that system.

### Conclusion

Understanding the ways that the regulatory regimes that have grown up to govern capital markets and banking address the different incentives of money and equity claimants is critical to understanding the challenges posed by the shadow banking system. The current regulatory architecture was not designed to accommodate market-based institutions that could produce money claims. Nor does any single theoretical frame suffice to capture the benefits and costs of shadow banking. Only by recognizing the limits of established theoretical frames and the shortcomings inherent in the current regulatory architecture can we hope to create the new paradigm required for shadow banking. The information dynamics highlighted here are central to that challenge. There is no easy fix, but by understanding the unique set of dynamics at play in this space, policymakers and other experts can begin to appreciate the ramifications of the decisions they are making.
